

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

LECTURES ON THE PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY, BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXIV., DELIVERED MARCH 25, 1833.

GENTLEMEN,—The specific and malignant disease, known by the name of *cancer*, may begin either as a molecular deposition in the tissue affected, from a derangement of its nutrition, or as a deposition of the heterologous matter upon what Professor Carswell terms a *free surface*, as, for instance, that of a serous membrane; here it is, then, in the form of a secreted matter. It generally has two stages, namely, *that of induration*, or *scirrhus*, as it is termed, the first shape in which the disease usually presents itself; and *that of ulceration*, which is a later condition of it.

It would lead, I think, to less confusion, if *scirrhus*, a term originally denoting any kind of hardness, were restricted to the induration, which is characterised by the texture peculiar to cancer, and marked by a decided tendency to cancerous ulceration. Had this rule been observed by the old surgeons, some parts of their works would have been more remarkable for correct descriptions, and more intelligible than they are found to be, with reference to the pathological condition of various textures, described as being affected with *scirrhus*. I believe all well informed surgeons of the present time only use the term *scirrhus* in the sense that I have explained.

The disease, in the stage of *scirrhus*, is also sometimes denominated *occult cancer*; and, in the ulcerated stage, *open cancer*, or sometimes *carcinoma*. I think that when the latter word is employed, the generality of surgeons now signify more particularly the ulcerated form of the disease. There is no uniform custom, however, about this point; and sometimes *carcinoma* is only synonymous with *cancer*.

Scirrhus, at its commencement, occupies a

minute and limited space; it may be confined to one of the acini of the liver, as Professor Carswell has ascertained; in the breast, it is commonly of a globular form, and irregular and craggy, as it were, on its surface. It afterwards enlarges, though rarely in the degree or with the quickness exemplified in many tumours of a different nature; it also continues to be moveable for a certain time; but has a tendency to become fixed by attachments to the neighbouring textures, at an earlier period than what is observed with respect to most other swellings.

Scirrhus is likewise remarkable for its excessive firmness, its cartilaginous, or, as it is sometimes expressed, its stony hardness. The substance of it, however, is not one uniform, homogeneous mass, but it is intersected by *septa*, or bands, the interstices of which are filled with a yellow, grey, or light brown, pulpy, friable substance. These bands, or *septa*, are observed to diverge, as they proceed from the centre of the disease, sometimes radiating, as pathologists are fond of expressing themselves, a considerable way into the surrounding textures, so as to extend the same morbid action to them. The *septa*, now described, have a tough consistence, and are very much like a ligamentous tissue.

When a section is made of a *scirrhus*, a central point, or nucleus, may be observed, from which these dense ligamentous bands proceed towards the circumference. Sometimes the larger bands subdivide into smaller ones, which follow a course similar to that of their trunk, and ramify very regularly, or the bands may pursue from the first an irregular and intricate course, often uniting with and crossing one another, so as truly to present, when minutely inspected, a retiform appearance.

Frequently, in a more advanced stage of the tumour, the greyish matter, interposed between the firm tough *septa*, appears broken down or removed, its place being occupied by a glairy or a turbid fluid, by a very soft, pulpy, semi-liquid substance, or blood itself.

Gentlemen, I may next inform you, that primary *scirrhus* and *cancer* are most commonly noticed in glandular or secreting organs,—as the female breast, the skin, the mucous

tissues, the tongue, the cardiac and pyloric portions of the stomach, the cervix uteri, the rectum, the lips, especially the lower one, and the glans penis. The testicle and ovaries are also liable to cancerous disease. Those parts, which I have specified, are some of the principal ones on which cancerous disease makes its *primary* attack; but many other textures and organs may become the seat of it secondarily; as, for instance, the absorbent glands, the lungs, the liver, and even the bones. You know, gentlemen, from what I have said in former lectures, that, in persons who have long suffered from carcinoma, portions of the natural structure of their bones are absorbed, and a scirrhus substance is deposited in their place. This fact is sometimes exemplified in the ribs and sternum; and I now show you the upper part of a cranium, taken from a person who died of cancer of the breast, and you may plainly see the secondary effects of the disease on the parietal bones. Probably, if the viscera of the same individual had been carefully examined, the cancerous texture might also have been traced in several of them. I attended a gentleman's coachman very lately, in Montague-street, Russell-square, for carcinoma of the bladder, and the effects of this disease on the skeleton were such, that one of the ribs and the left thigh bone underwent spontaneous fractures previously to the patient's death. The rib and the thigh-bone I mean shortly to place in the museum of this University. As secondary effects of cancer, beginning in the lower lip, scirrhus formations have been noticed in the walls of the heart itself. A case, illustrative of this fact, was lately in St. Bartholomew's Hospital, and the particulars of it have been inserted in the Medical Gazette, by Mr. W. M. Coates. The primary cancerous affection was situated, in this instance, in the lower lip; a form of the disease, as Mr. Coates correctly observes, not unfrequently regarded as entirely local.

When cancer is regarded as a genus, comprehending in its species, scirrhus, common vascular sarcoma, pancreatic, medullary, and mammary sarcoma, and fungus hæmatodes, (the view adopted by Professor Carswell,) of course, many other parts may be set down as very liable to carcinoma, besides those now enumerated by me. Those diseases he considers to be of the same family, 1st, because they often present in the early periods of their formation certain characters common to all of them, however much they may differ from each other in their subsequent periods. 2ndly, because they all terminate in the gradual destruction, or transformation of the tissues they affect. 3rdly, because they all have a tendency to affect several organs in the same individual. 4thly, because they all possess, though in various degrees, the same reproductive character. Dr. Carswell describes two states of the heterogeneous deposit, of which these diseases consist; in one it has little or no tendency to become organised; its form and arrangement appear

to be determined chiefly by external circumstances; and its formation and subsequent increase are entirely dependent on the nutritive function of the organ in which it is contained. In the second state, this deposit exhibits, on the contrary, a greater or less tendency to become organised; it possesses within itself properties, by means of which its subsequent arrangement and development are affected, independently of the nutritive function of the organ, in which it is formed, except in so far as the materials of its growth may be derived from this source. The first example Professor Carswell calls *scirrhus*, the second *cephaloma*. In this course of lectures, however, when I speak of scirrhus and cancer, only those forms of disease are signified, which have been alluded to in the commencement of the present discourse. The others will be considered hereafter. There, are, however, many interesting observations in Dr. Carswell's *Illustrations of the Elementary Forms of Disease, relative to Cancer and Fungus Hæmatodes*, which bring the subject completely into a new light; and which will no doubt receive that candid attention from the profession, to which his meritorious exertions have ample claims. Thus, one circumstance which he observes, and which is new, I believe, to the generality of pathologists of this country, is, that numerous examples might be given of scirrhus, medullary sarcoma, and fungus hæmatodes, as they are commonly called, originating in the same morbid state, and passing successively from the one into the other, in the order now enumerated. Indeed, he says, that we often meet with all the varieties of what he terms scirrhus and cephaloma, not only in different organs of the same individual, but even in a single organ. And of so much importance has it appeared to Professor Carswell to establish this fact, that the coloured representations in his second Fasciculus are chiefly devoted to its illustration.

Scirrhus and cancer very rarely occur in subjects under thirty years of age, and not often in any individuals under forty or forty-five. The late Sir Everard Home, however, met with an instance of a true cancerous formation in the breast of a young woman under twenty. This was a rare occurrence, with reference to the breast, or cancer in general; yet I may tell you, what you will not find noticed in treatises on surgery, it is not very uncommon for scirrhus of the uterus to be met with in patients under thirty. We have had some melancholy instances of this fact amongst the patients of the Bloomsbury Dispensary.

In consequence of the female breast and the uterus being particularly often the seats of cancer, the disease more frequently afflicts women than men; and, gentlemen, I may remark, that there is another circumstance, affording an additional reason for females being more liable to this intractable disorder; namely, the change that occurs in

their constitutions about the period of life, when the menses cease. Hence, between the ages of forty and fifty, you find that they often begin to suffer from scirrhus and cancerous affections.

It is generally believed that various common tumours, ulcers, and pimples, may change into malignant ones, and assume the cancerous action, under the influence of particular states of the constitution. Thus, when a female has a tumour in the breast, not originally of a malignant nature, another morbid action may be excited in the part about the period of life when the menses stop, and the disease may then assume the character of scirrhus or carcinoma. Nay, a tumour of the breast, brought on by a blow, and beginning to all appearances with common inflammation, in a seemingly healthy woman, long before this critical period of life, will sometimes leave a hardness behind that will then change into scirrhus and cancer. I suspect, however, that common adipose tumours never degenerate into cancer.

Swelling is frequently considered not to be an essential feature of scirrhus and cancer. On this point, I think, Sir Charles Bell has delivered one of the most accurate statements. In cancerous diseases of the breast, there is not always an increase in the dimensions of the whole breast, but often an actual diminution of its total bulk. But what is true of the breast, or mamma, is not true of the disease, more generally considered; for the proper structure of the mammary gland frequently either shrinks, or is compressed by the scirrhus new-formed deposition; and sometimes the quantity of surrounding fat is lessened by absorption; and the consequences are, that the whole mass is less than the natural breast, or than what the breast was, previously to the commencement of the disease. Still it is a fact, that the disease is properly a tumour—it is indeed a preternatural growth—a new formation.

The difference in the feel of scirrhi depends very materially upon the quantity of fat around them; if much of the adipose substance be absorbed, you will readily feel the irregular knotty form of the disease; but, when a good deal of fat remains, the breast seems large, full, and smooth, streaked perhaps with blue dilated veins, and having sometimes an ulcerated aperture in its centre.

However, after a scirrhus of the breast has existed a certain time, its character is generally denoted by the puckered state, and dull leaden or brownish colour of the integuments, the knotty and uneven feel of the disease, the occasional sharp darting pains in the part, its fixed attachment to the skin above, and to the pectoral muscle underneath it, and the early retraction of the nipple, a circumstance alleged to be produced by the extension of some of the scirrhus bands between the lactiferous ducts, whereby its spongy texture is destroyed.

A true scirrhus tumour of the breast, one disposed to be attacked by cancerous ulcera-

tion, is known to a man of experience by its remarkable hardness; its great weight in proportion to its size, which is seldom considerable; the lancinating pains occasionally felt in it, and its close connexion with the gland of the breast; so that, when moved, this gland moves along with it. The diagnosis will also be much assisted by reference to the patient's age.

With the exception of fungus hæmatodes, few other diseases so completely involve in their ravages every kind of tissue, skin, muscle, mucous membrane, cellular substance, lymphatic glands, &c.

In ordinary tumours, the skin does not usually become affected, till they have attained a considerable size; but, in true scirrhus, the skin generally becomes adherent to the morbid mass, and both discoloured and puckered.

Although a scirrhus of the breast may remain for months, and even for years in a quiet state, without advancing to ulceration, the disease is generally observed to ulcerate before the new formation has acquired great bulk. A large chasm is then commonly produced, partly by a sloughing, and partly by an ulcerative process; and an excoriating, peculiarly foetid ichor is discharged, often in such abundance, as to excite surprise in a person not accustomed to the view of this fatal disease. Its smell is also so different—so much more offensively disagreeable than any other kind of discharge, that, when once you have been acquainted with it, you will never forget it; and, afterwards, when a patient with ulcerated cancer is near you, your nose will tell you of his approach, though your eyes may be shut.

When the sloughs have been detached, partial but ineffectual attempts at reparation are made. Even granulations form; but they are greyish, hard, warty, and endowed with but little vitality; never covering the whole surface, but rising only at certain points, and soon changing into fungous growths of extraordinary hardness. However, sometimes cancerous ulceration really stops; cicatrisation even occurs at particular points; and a degree of mitigation is experienced; but the part never heals to any great extent—never becomes healthy. The margins of the sore become indurated, irregular, and twisted in various ways; in some places everted, in others inverted, or turned downwards and inwards.

The disease extends to other parts, and often to remote situations; the absorbent glands especially become affected. The disease is propagated from one gland to another, so that, after all the axillary glands are affected, those which lie under the clavicle, in the neck, or in the upper part of the chest, or under the sternum, in the course of the internal mammary vessels, become diseased.

The absorbent glands are indeed frequently affected in an early stage of cancer, generally becoming very much indurated, and having

almost the density of cartilage; but sometimes becoming softened and broken down at several points, and containing a purulent, or bloody fluid. The lymphatic vessels, entering or leaving the glands, also sometimes feel hard and wiry. In the advanced stage of cancer of the breast, so seriously is the function of the absorbents of the nearest arm sometimes impeded, that the limb is in a constant state of painful œdema, and rendered completely useless. In ulcerated cancer, frequent hæmorrhages take place from the fungous granulations; and these repeated losses of blood, joined with the constant pain and irritation of the disease, the want of sleep, and the progressive extension of the disorder to other parts of the system, soon bring the patient into the lowest state of debility. Nausea and disturbance of digestion now come on, followed by a distressing and incessant cough. Pains in the chest and oppression of the breathing increase from day to day; the patient becomes wan, sallow, and emaciated; the pulse rapid and faltering; and death at length puts an end to this scene of misery, often preceded by anasarca.

Gentlemen, you know that one deplorable effect of cancer in its inveterate form is to produce an extraordinary fragility of the bones, which are apt to be broken by the most trivial causes, and even by the ordinary action of the muscles attached to them. I have also informed you, that, in some of these cases, masses of schirrous matter are deposited in the vertebræ, cranium, sternum, or long cylindrical bones, in lieu of their proper texture.

When cancer attacks the skin or a mucous membrane, an induration or warty lump is first produced, which afterwards ulcerates, and the sore has a particularly hard base. The ulceration gradually assumes the appearance of cancer, and soon cannot be distinguished from a sore that has been the result of scirrhus in other textures.

With regard to the *causes of cancer*, one important question is, whether the disease is a local or a constitutional one? Its origin is frequently ascribed to blows, pressure, and external injuries; but, I believe, the whole history of cancer tends to prove, that, although it may follow a slight contusion, the scratch or irritation of a little wart or excrescence, that has been stationary and harmless for years, or a common inflammation or abscess of the breast, these circumstances can only be regarded as *exciting* causes, which would not have brought on the disease, had there not been a certain state of the constitution qualifying it for the production of the specific structure of a cancerous tumour, and the peculiar morbid actions by which the nature of cancer is distinguished.

I do not adopt the views of some surgeons, who get rid of this question by saying, that cancer is at first a local, and afterwards a constitutional, disease. If cancer were not always dependent upon constitutional causes,

why should it be so rare in persons under thirty years of age? Why should it be so common in women at the critical change which affects their system about the age of forty-five? Why also should the disease be so frequent in particular families, as to excite the suspicion of its being hereditary? At all events, we must believe that the disease is the effect of a specific action in the part, preceded by some peculiar state of the constitution, without which such specific action would not have taken place. It is very true, that you occasionally meet, though very rarely, with the true cancerous texture in young persons, and that you are not always able to trace any defect in their constitutions; but, because you cannot discover it, you are not to presume that it certainly does not exist; and, as far as you can reason from other examples of the disease, you must infer, that when a scirrhus or cancerous disease forms either in a young or old person, there must be peculiarities in the constitution, without which such a complaint would not have been produced. As Professor Carswell justly observes, hundreds and thousands of individuals are daily affected with inflammation, without this local disease being followed by any other than its usual effects; a fact placing in the clearest light the necessity of a previously existing modification of the economy, as the immediate and essential condition of the speciality of the heterologous formations, when they occur in conjunction with inflammation. He illustrates this remark by the following case:—an individual has a tumour on the external surface of the body, presenting the characters of some variety of cancer. He has an attack of pneumonia or pleurisy, or both, of which he dies in the course of a few days. On examining the diseased lung, or pleura, we find, instead of an effusion of serosity, coagulable lymph, or pus,—the usual products of inflammation—that the lung is converted into a solid mass, resembling a section of fresh pork. It is in the state of scirrhus; and the pleura is studded with tumours of various sizes, composed of a similar kind of substance.

A very curious and interesting fact, in relation to this part of the subject, is adverted to by Professor Carswell in his highly valuable work, now publishing, entitled "*Illustrations of the Elementary Forms of Disease*:" I allude to the *formation of carcinoma in the blood*. According to his views, cancer is divided into *scirrhus* and *cephaloma*, of both of which there are varieties, to which the terms *vascular*, *pancreatic*, *medullary sarcoma*, *fungus hæmatodes*, &c. are usually applied. He states, that the heterologous substance, which constitutes the two species of carcinoma, is present in the vessels which ramify in carcinomatous tumours, or their immediate vicinity; and that it can be traced from the trunks into the branches or capillaries. Also, that it is found in vessels having no direct communication with a cancerous part, as when

it is confined to a small extent of the vena portæ; and lastly, in blood that has been effused into the cellular tissue, and on the surface of organs. He observes, that the divisions of the vascular system, in which the carcinomatous substance has been found, are the venous and the capillary. The formation of carcinoma in the blood, he says, cannot remain a matter of doubt; and he adopts the belief, that the presence of an organised product in the blood can have no other source but the blood itself; and cannot be introduced into this fluid by absorption. From this view of the origin of carcinoma, says Professor Carswell, its formation in the intimate structure, and on the free surface of organs, follows as a matter of course. The material element of the disease is separated from the blood, and deposited under a variety of circumstances, which modify, in a greater or less degree, the form, bulk, colour, and consistence, which it afterwards presents in the several periods of its development. Dr. Carswell, therefore, does not agree with several pathologists, who limit the seat of cancer to any one tissue, nor does he ascribe its origin to any modification of structure, or special organisation. Here, however, we are to remember, that Dr. Carswell's views of carcinoma comprise, as varieties of this disease, several cases, which have usually been separated from it, not being regarded as entitled to the classification which he has assigned to them.

Scirrhus and cancer, in the ordinary sense of these terms, are common at all ages between 30 and 70. Sir Everard Home met with a single instance of the true scirrhus texture in a person only 15 years of age; and Sir Astley Cooper, in all his long and extensive experience, never saw cancer in more than two individuals, who were less than 30. Yet, as I have already stated, we have had several examples of scirrhus wombs in young women under 30, as verified by *post mortem* examination. The most common period for its commencement is the age of 50.

Another fact, which is curious, in relation to the influence of age on cancer, is, that when the disease occurs in persons of very great age, it is slow in its progress, and does not, in general, materially shorten their lives.

Cancer is known to all the world to be one of the most intractable diseases to which the human body is liable. When you consider it as a new formation—as an adventitious deposit, accompanied by the peculiar texture and organisation, which I have described, accompanied also by some peculiarity of constitution, or modification of the economy,—you must see, that the power of medicine can have little or no influence over the disease. Yet, we may not be justified in asserting, that scirrhus and cancer are absolutely incurable. Not very long ago, I attended a young woman, under 30, in Great Ormond-yard, Queen-square, who died of scirrhus and cancerous ulceration of the womb, as ascertained by dissection, the parts having been removed, and preserved by Mr.

Miller, of the Bloomsbury Dispensary. Her mother, who was living in the same house, and far advanced in years, had had both her breasts entirely destroyed by cancerous disease, which had terminated in extensive sloughing. Here, no doubt, the whole scirrhus mass in each breast had been separated by the process established by nature for the detachment of the sloughs, and with them, I presume, the scirrhus bands, radiating from the tumour into the contiguous parts, were also thrown off, after which the ulcers healed like any common sores. The front of the chest on each side presents a most irregular mutilated appearance; the woman cannot now be less than 80 years of age.

As however this mode of termination of cancer is on the principle of extirpation, accidentally brought about by nature herself, strictly speaking, it may not affect the truth of the general observation, that cancer, whether in the state of scirrhus or carcinomatous ulceration, is positively incurable by any means, except such as are calculated to remove or destroy the whole of the parts affected. And, even when this is done, owing to the continued influence of constitutional causes, a recurrence of the disease, either in the same part or others, will always follow in a certain proportion of cases thus treated.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE VI.

Pathology and Treatment of Gastritis.

GENTLEMEN,—I shall begin to-day with the treatment of chronic gastritis, and I beg of you to bear in mind what I mentioned at my last lecture, that this disease, in its true and pathological meaning, is not sufficiently recognised. In general, it gets some wrong name or other; and as many practitioners are in the habit of prescribing for names, it generally meets with wrong treatment. It is called every thing but what it is, and its remedies are as numerous and as various as its appellations. By some, it is called dyspepsia, and is treated with bitters, astringents, and stimulants; by others, it is termed constipation, and treated with purgatives; the school of Abernethy look upon it as an affection of the liver, and prescribe blue pill and black draught; others give it the name of hypochondriasis, and exhaust the whole catalogue of nervous and anti-dyspeptic medicines in attempting its removal; in fact, it is called every thing but what it is, and the result is an unsteady and mischievous empiricism.

You will recollect a fact, to which I alluded in my last lecture, that the physiological condition of the stomach requires, that it should

be subject to frequent excitements of its vascular tissue, and that, this increased vascularity being the consequence of a natural process, digestion is, generally speaking, exempt from any kind of danger. If the brain or lungs were to experience an equal increase of vascularity, sensibility, and excitement, the consequences would be dangerous, or perhaps fatal, and we should have pulmonary and cerebral diseases produced. But though the stomach enjoys such a remarkable exemption from the liability to acute inflammation, under circumstances of repeated vascular excitement, yet the slow, insidious, chronic gastritis is an exceedingly common affection. I feel convinced that many persons die of it, or of the extensive class of fatal diseases which it frequently induces. But I rejoice to say, that we have good reason to hope, that the progressive amelioration of medical science will materially diminish the amount of human suffering from this cause. As physiological medicine advances, the number of those who die of unrecognised chronic visceral disease will be less and less, because diagnosis will become more extended and certain, and practice more simple and successful.

The first thing you should do, when called to treat a case of dyspepsia, is to ascertain whether it be a purely nervous disease, or a chronic gastritis. The majority of practitioners give themselves no trouble about this matter, not recognising the fact, that, of the number of dyspeptic persons who seek for medical advice, a considerable proportion are really labouring under a chronic gastritis, and forgetting, that, in consequence of long continued functional injury, what was at first but a mere nervous derangement may afterwards become complicated with organic disease. You must also bear in mind, that the stomach is perhaps placed under more unfavourable circumstances for bringing about a cure than any other organ, because the life of the individual demands that the stomach, though in a state of inflammation, should still continue to perform its functions. In treating diseases of other organs, you will have the advantage of a comparative state of rest, but, in a case of the stomach, if you wish to preserve life, you cannot prohibit nutriment, and consequently you must run the risk of keeping up these periodic vascularities which its condition requires, which, though harmless in health, become a source of evil when the stomach is diseased. The obvious deduction from this is, that the cure of a chronic gastritis depends as much upon regimen as upon medical treatment, and particularly where the symptoms have arisen from long continued excitement, as in the case of persons who live highly. Here the treatment chiefly depends on regulating the diet, and if your patient has sense enough to live sparingly for a few weeks or months, you may be able to effect a cure without other treatment. The great error is, that most practitioners attempt to cure the disease by specifics, and when these fail they then

go to the symptomatic treatment, prescribing sometimes for acidity, sometimes for nausea, sometimes for flatulence, sometimes for constipation, or "the liver," or debility.

You should be careful in the examination of such cases, and should try to ascertain, whether these symptoms may not depend upon inflammation of the stomach; for as long as the patient is in this state, the less you have recourse to symptomatic or specific treatment the better. It is hard to mention one single medicine which in this state will not prove stimulant, and if the stomach be unfit for stimulants, it must be unfit for the generality of medicines. There are numbers of cases of persons labouring under chronic gastritis, which have been cured by strict regulation of diet, and by avoiding every article of food requiring strong digestive powers. We find that articles of diet vary very much in this respect; some are digested with ease, some with pain. We might express this otherwise, by saying, that some require very little excitement of the stomach, and others very great vascular excitement. Patients, in this irritable state of stomach, can scarcely bear any kind of ingesta; and when you consider the great vascularity, thickening of the mucous membrane, and tendency to organic disease, you will be induced to think that every thing entering the stomach should be of the mildest kind, and not requiring any powerful determination of blood to that organ.

If you continually prescribe for symptoms, neglecting or overlooking the real nature of the disease, giving arsenic to excite the system, and iron to remove anæmia, and bitter tonics to improve the appetite, and alkaline remedies for acidity, and carminatives to expel flatus, you will do no good; you may chance to give relief to-day, and find your patient worse to-morrow; and at last he will die, and you may be disgraced. On opening the stomach after death, you are astonished to find extensive ulceration, or, perhaps, cancerous disease. Very often, in such cases, practitioners say that it is cancerous disease, and that no good can be done. But the thing is to be able to know, when you are called to a case, whether it is a case of mere nervous dyspepsia, or chronic inflammation of the stomach. Some of the best pathologists think that most of the cancerous affections of the stomach are in the beginning only chronic inflammations of that organ.

I believe we have not yet in this country adopted the plan of moderate application of leeches to the epigastrium in cases of chronic gastritis. I have seen in many cases great benefit result from the repeated application of a small number of leeches to the epigastrium, at intervals of two or three days. Here is a point which you will find very useful in practice. You will meet with cases which have lasted for a long time; cases where there is strong evidence of organic disease, and which have resisted the ordinary dyspeptic treatment. You will be called frequently to treat these three

different cases,—where the disease has been of long duration, where there is distinct evidence of organic disease, and where the disease has resisted the ordinary dyspeptic treatment. Here is a case of a patient labouring under what is called indigestion, and which has resisted the stimulant, and tonic, and purgative treatment.—Here is one fact. In the next place, the disease is chronic, and the probability is, that there is inflammation, and consequently that there is chronic gastritis. Now if, in such a case, you omit all medicine by the mouth, apply leeches to the epigastrium, keep the bowels open by injections, and regulate the diet, you will often do a vast deal of good. I have seen, under this treatment, the tongue clean, the pain and tenderness of the epigastrium subside, the acidity, thirst, nausea, and flatulence removed, the power of digestion restored, and all the symptoms for which alkalies, and acids, and tonics, and purgatives were prescribed, vanish under treatment calculated to remove chronic inflammation of the stomach.

What is next in importance to regulated regimen and local bleeding?—A careful attention to the bowels, which in chronic gastritis are generally constipated, and this has a tendency to keep up disease in the upper part of the digestive tube. Is this to be obviated by introducing purgative medicine into the stomach?—No. If you introduce strong purgative medicine by the mouth, you will do a great deal of mischief. You must open the bowels by enemata, or, if you give medicine by the mouth, by the mildest laxatives in a state of great dilution. A little castor-oil, given every third or fourth day, or a little rhubarb with some of the neutral salts, will answer in most cases. The diet, too, can be managed, so as to have a gently laxative effect. The use of injections is, however, what I principally rely on. I have seen many cases of gastritis cured by the total omission of all medicine by the mouth, by giving up every article of food which disagreed with the stomach, and by the use of warm water enemata. I have seen this treatment relieve and cure persons whose sufferings had lasted for years previous to its employment, and who had been considered by eminent practitioners to labour under organic disease of an incurable nature. It is important that you should bear this in mind. The old purgative and mercurial treatment of gastritis, I am happy to say, is rapidly declining; and British practitioners are now convinced, that they cannot cure every form of dyspepsia by the old mode of treatment. I do not deny that many diseases of the digestive tube may be benefited by the mild use of mercury and laxatives, but I think I have every reasonable and scientific practitioner with me in condemning the unscientific routine practice, which was followed by those who took the writings of Abernethy and Hamilton for their guide. I do not say that,

where cases of gastric inflammation, treated after the plan of Mr. Abernethy, have proved fatal, the medicines have destroyed life; I merely assert that the patients died of inflammation, over which these medicines had no control; and the error lay in mistaking and overlooking the actual disease, as much as in its maltreatment. You will find some practitioners (they are becoming fewer in number every day), who seem to have but two ideas, the one a purgative, the other a pot full of feces; but the connecting link,—the gastro-enteric mucous membrane,—that vast expansion, so complicated, so delicate, so important, seems to be totally forgotten. But practitioners are now beginning to see that purgatives are not to be employed empirically; that they should be administered in many cases with great caution, and with a due attention to the actual condition of the alimentary canal, and that they have been a source of great abuse in the medical practice of these countries.

Next to leeching and a proper regulation of the bowels is the employment of gentle and long-continued counter-irritation over the stomach. This may be effected by the repeated application of small blisters, or by the use of tartar emetic ointment. I have been in the habit of impressing upon the class, that the tartar emetic ointment used in these countries is too strong, the consequence of which is an eruption of large pustules, which are excessively painful, and often accompanied with such disturbance of the constitution as amounts to symptomatic fever. In fact, tartar emetic ointment of the ordinary strength produces so much irritation, that few patients will submit to it long. The form which I recommend you to employ is the following:—Take seven drachms of prepared lard, and, instead of a drachm of tartar emetic, which is the usual quantity, take half a drachm, directing in your prescription (this is a point of importance) that it be reduced to an impalpable powder; and you may add to it what will increase its action, one drachm of mercurial ointment. This produces a crop of small pustules, which give but little pain and are easily borne; and the counter-irritation may be kept up in this way for a considerable time, by stopping, for a few days, until the eruption fades away, and then renewing the friction. I have often seen the utility of this remedy exemplified in cases of chronic gastritis, where the symptoms of gastric irritation, which had subsided under the employment of friction with tartar emetic ointment, returned when it was left off, and again vanished when it was resumed. The case of the celebrated anatomist, Beclard, furnishes a very remarkable proof of the value of a well-regulated diet and repeated counter-irritation in the treatment of this disease. While he was engaged in the ardent prosecution of his professional studies he got an affection of the stomach, which he considered to be a chronic gastritis, and immediately put him-

self under a strict regimen, using at the same time repeated counter-irritation. He kept up the counter-irritant plan for a considerable length of time, for he found that, when he discontinued it, the gastric symptoms had a tendency to return. In this way he got completely rid of the disease. Several years afterwards he died of an attack of erysipelas; and, on opening his stomach, the cicatrix of an old ulcer was discovered in the vicinity of the pylorus, which was exactly the spot to which he had referred his pain during the continuance of his gastric affection.

Gentlemen, there is perhaps no science in which the motto "*medio tutissimus ibis*" is of more extensive application than in medicine. Some physicians on the Continent, particularly the disciples of Broussais, having repeatedly witnessed the advantages of strict regimen and local depletion in chronic gastritis, have pushed this practice too far. They seemed to forget that the system requires support and nutrition, which can be effected only through the agency of the stomach; they saw the evils which result from the use of stimulating food in cases of chronic gastritis; and, looking to these alone, they ran into the opposite extreme, the consequence of which was, that they kept their patients so long upon low diet, that they actually produced the very symptoms which they wished to remove. The patients became dyspeptic from real debility of the stomach and the whole frame. You remember a general law of pathology to which I have alluded on a former occasion, and which I shall again mention, as it illustrates this point, namely, that opposite states of the economy may be accompanied by the same symptoms. Thus we observe, that palpitation may depend on two different causes—on a sthenic or asthenic condition—on the presence of too much or too little blood in the heart. Now, it frequently happened that patients, labouring under chronic gastritis, and who had been treated for a long time after the strict plan adopted by the Broussaists, finding themselves not at all improved, went to other physicians who had different views, and were rapidly cured, by being put upon a full nutritious diet. In this way numerous cases, which water diet and depletion had only aggravated, were relieved, and the consequence was, that a mass of facts was brought forward and published, not long since, by a French author, against the antiphlogistic treatment of dyspepsia and chronic gastritis. It must be stated, however, that the cases which he published were chiefly those in which the depleting system had been carried to excess, and that they cannot, therefore, be received as proofs of the value of a stimulating diet in the treatment of chronic inflammation of the stomach. Bear this in mind; the sooner you can put your patient on a nutritious diet the better will it be for him. It would be absurd to keep a patient for many months, as the Broussaists have done, on slops and

gum-water. It will be necessary for you to feel your way and improve the diet gradually. Commence by giving a small quantity of mild nutritious food; if your patient bears it well, you can go on; if the gastric symptoms return you can easily stop. If a small portion of the milder species of food rests quietly on the stomach, you may increase it the next day or the day after, and thus you proceed to more solid and nutritious aliment, until the tone of your patient's stomach regains the standard of health. Never lose sight of this fact, that you may have a case of dyspepsia depending on a chronic gastritis, in which, though you remove the inflammation by a strict antiphlogistic treatment, you may not by this remove the dyspepsia; and if you continue to leech, and blister, and starve your patient *after the inflammatory state be removed*, you will do great injury. Such a patient, falling into the hands of another practitioner who treated him on a different system, might be relieved, and his case quoted against you and your treatment, though this, at the commencement, was judicious and proper.

With respect to internal remedies, the school of Broussais think that there is nothing required but cold water and gum. This is going too far. In a former lecture I have drawn your attention to the fact, that in the treatment of acute inflammation there is a point where antiphlogistics should cease, and where tonics and stimulants are the most efficient means of cure. Of this fact the disciples of Broussais appear to be ignorant, and they consequently declared against every remedy for chronic gastritis except leeches and cold water. Now is this right? I think not. We find that, in all cases of gastric inflammation, a change in medication seems to be useful at some period of the disease, that is a change from antiphlogistics to tonics and stimulants, and I believe that in cases of chronic gastritis these remedies may be used with very great advantage, having, of course, premised depletion and counter-irritants. I believe too that most of the remedies, which we see every day unsuccessfully employed, would have acted beneficially, if the preparatory treatment which I have mentioned had been adopted. Among the best remedies of this kind is the oxide of bismuth; I have seen more benefit from the use of this than of any other medicine, after the treatment already alluded to. Generally speaking, the list of internal remedies for chronic gastritis is very small, but after the use of antiphlogistics you may prescribe the vegetable tonics and oxide of bismuth with advantage. The most decidedly valuable remedy, however, in the after stage of a chronic gastritis is the acetate of morphia, which I am convinced has a very powerful effect in allaying chronic irritation of the stomach. Dr. Bardsley of Manchester, in one of his published works, entitled "*Hospital Facts and Observations*," adduces many cases of gastric irritation which were completely relieved by

the use of this remedy, and I am perfectly satisfied of the truth of his statements. It may be said that Dr. Bardsley's cases were only instances of dyspepsia. But as his cases were extremely numerous, some of them of long standing, and the symptoms very severe, the great probability is, that some of them at least must have been cases of chronic gastritis. I know very few books, the perusal of which I would more strongly recommend to you, than Dr. Bardsley's accurate and instructive work. The great besetting sin of medical writers is, that their statements of successful practice are grounded on a very limited number of cases, or that, in publishing the result of their practical investigations, they only give their successful cases, and leave out those, in which the treatment recommended has been found inefficacious. Yet this is a circumstance which should never be neglected. If a man declares that he has discovered a cure for gastritis, or dyspepsia, and brings forward one hundred cases in which the remedy has done good, the statement is still unsatisfactory and insufficient, because there may be one thousand cases in which it has totally failed. Unless he comes forward and gives both his successful and unsuccessful cases, of what value are his statements? Dr. Bardsley, with the candour and good sense which always characterise the philosophic inquirer, gives the result of *all* his cases, forms them into tables, and then leaves his readers to judge for themselves. From an inspection of these tables, you will be convinced of the efficacy of acetate of morphia in the treatment of chronic gastritis. I have been in the habit of using it with the most gratifying results after leeching, regulating the diet, and paying proper attention to the state of the bowels. There are some forms of the disease in which it is more useful than others. The particular form, in which it proves most serviceable, is where there is a copious secretion of acid from the stomach, (that form in which all kinds of alkalies have been exhibited), where severe pain and constant acidity are the prominent symptoms. Here I have seen the acetate of morphia act exceedingly well. You may begin with one-twelfth of a grain, made into a pill with crumb of bread, or conserve of roses, twice a-day; the next day you may order it to be taken three times, and you may go on in this way until you make the patient take from half a grain to a grain and a half in the 24 hours. I shall here mention the circumstances of a case, which I do not mean to bring forward as an instance of cure, but as an illustration of the extraordinary power which acetate of morphia possesses in relieving gastric irritation. A gentleman of strong mind and highly cultivated intellectual powers, which he kept in constant exercise, got a severe chronic gastritis; his appetite completely declined; he had frequent vomiting of sour matter; foetid eructations; and such violent pain in the stomach, that he used, when the attack came on, to throw him-

self on the ground, and roll about in a state of indescribable agony. He applied to various practitioners, had several consultations on his case, and the opinion of the most eminent medical men was, that he had incurable cancerous disease of the stomach. These symptoms continued for several years, but for the last two or three years they were quite intolerable. He had repeated cold sweats, vomited every thing he took, even cold water, was reduced to a skeleton, and led a life of complete torture. Under such circumstances he tried, for the first time, by my advice, the acetate of morphia. He tried it first in doses of one-tenth of a grain three times a-day, and experienced the most unexpected relief. On the third day all his bad symptoms were gone. He had no pain, no vomiting, no sweats; his spirits were raised to the highest state of exhilaration, and he thought himself perfectly cured. He went out in the greatest joy, visited all his friends, and told them that he had at last got rid of his tormenting malady. In the evening he joined a supper party, indulged pretty freely, and next morning had a violent hæmatemesis, to which he had been for some time subject. All his old symptoms again made their appearance. He again had recourse to the acetate of morphia, and again immediately experienced relief, but the vomiting of blood again returned, so that he discontinued the remedy. This gentleman is now in the enjoyment of good health. He regulated his diet, left off all medicine by the mouth, used warm water injections, and thus recovered from his supposed cancer.

I do not bring this case forward as an instance of the curative effect of acetate of morphia, but as an instance of its powerful effect in allaying gastric irritation. I could adduce other cases in proof of its value in the treatment of the after stage of chronic gastritis, and particularly of that form in which pain and acidity are the prominent symptoms; but I perceive my time has nearly expired. At my next lecture, I shall give some other particulars connected with this subject, and then proceed to the consideration of diseases of the small intestine.

DR. O'BEIRNE'S REJOINDER TO MR. SALMON.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—I find that Mr. Salmon's reply to me is a general one; and that, by embracing a great variety of points, it is calculated to divert the mind from the subject of organic stricture of the rectum, upon which we are mainly at issue, and which we had mutually agreed to leave to the decision of two distinguished members of the profession. This course may suit his purposes but will not answer mine. For the present, therefore, my rejoinder shall be confined to fixing your at-

tention, and directing my observations, exclusively to the matter in arbitrio. But I reserve to myself the right of seizing an early opportunity to answer the other parts of Mr. Salmon's reply.

Before I proceed further in this matter, I regret to be under the necessity of making known, and animadverting upon, some of the circumstances, under which reports upon the subject in question have been laid before the profession. The circumstances are these:—By mutual consent Dr. James Blundell and Mr. Branshy Cooper became umpires on the difference between Mr. Salmon and me; yet week after week, and month after month, continued to elapse without bringing any decision from these gentlemen. Such delay, in deciding a matter so easy to be determined, induced me to believe that their investigations could not be very unfavourable to me, and that there was a hitch somewhere. Accordingly I wrote to Mr. Cooper, calling upon him for an explanation, and urging him to come to some decision on the question. His answer was to this effect:—that he had waited for, but had not received, Dr. Blundell's opinion; that his own had been long made up, and that it was decidedly in my favour. Shortly after receiving this intelligence, Mr. Oldknow's letter appeared in the *Lancet*, and, in the course of a few days more, Mr. Cooper inclosed to me a statement from Dr. Blundell, the same, in all respects, as that which you and the Editor of the *Lancet* have published; and I found that this statement contained facts, which appeared to me to be perfectly conclusive, as to the soundness of Mr. Cooper's decision. I had, therefore, these favourable documents in my possession so early as the middle of last November, and might easily have anticipated my opponent, by many days, in placing the result before the profession. But, instead of doing so, or taking any advantage of Mr. Salmon, I again wrote to Mr. Cooper, and submitted to him the necessity of slitting the preparations marked A and B in their whole length, before either he or Dr. Blundell could fairly come to a final decision. But it would appear, that Mr. Cooper was prevented from making this fair and considerate proposal, or interfering further in the affair, by a step which Mr. Salmon had taking in the mean time, namely, requesting Mr. Stanley and Dr. Ryan to inspect his preparations, and give their opinions on the contested points. Now, although these gentlemen are perfectly unexceptionable, and their characters and opinions above all suspicion of partiality, I submit to you and to the profession, that this step was a positive breach of a compact, mutually agreed to and acted upon for three months; and, on the part of Mr. Salmon, any thing but respectful or complimentary to either his own friend or to mine. He tells you, indeed, that he took this step in consequence of "finding they (Dr. Blundell and Mr. Cooper) differed so materially." But was it then, or is it now, the fact? Dr. Blundell is silent respecting any such disagreement;

Mr. Cooper says expressly, that his "observations bear a great resemblance to those made by Dr. Blundell, upon his inspection of the same preparations;" and I not only cannot see that any such difference exists between these gentlemen, but pledge myself to demonstrate, that they agree perfectly with each other. Let me suppose, however, that the umpires, originally appointed, differed as widely as the poles are asunder, and that this difference justified my opponent in calling in the aid of others without my knowledge or consent, would it not have been fair, and no more than fair, to have invited Mr. Cooper to be present at the inspection made by Dr. Ryan and Mr. Stanley? Yet this was not done; and that it ought to have been done will be evident from the fact, that, in consequence of the subject of organic stricture of the rectum being but very briefly touched upon in a part of one of the notes in my work, Mr. Cooper was obliged to call upon me for various explanations and definitions, before he became thoroughly acquainted with the exact nature of my views on the subject, or could come to a decided opinion on the question before him. It is clear, therefore, and it shall be my business to make it still clearer, that, on making their inspection, Mr. Stanley and Dr. Ryan had but one side of the question fairly placed before them.

The truth is, that Mr. Salmon, by being on the spot, has had great and obvious advantages over me, and has not been at all over-squeamish, or punctilious, in availing himself of them. In this controversy, also, he enjoys, and he knows it, advantages of another description, and of no mean importance. He is not, like me, defending his own views, but those which have been long and universally received; and, consequently, he can count upon seeing, ranged on his side, that great body of readers, who will not be convinced until they can no longer offer opposition, while I can only count upon the comparatively few, who are ready to embrace truth, let her come in ever so homely a garb, or from ever so humble a quarter. But let it not be supposed, that I mean to deprive my adversary of any one of these advantages, whether natural or acquired, or that it is my intention either to object to, or shrink from, any evidence that he has adduced. No, the cause of humanity and science spurns all such dexterous expedients, and demands to be pleaded boldly, frankly, and without subtlety, or evasion of any kind. In this spirit I shall now enter on my undertaking.

The exact nature and practical bearing of the difference between Mr. Salmon and me, on the subject of organic stricture of the rectum, do not appear to be fully understood, either by Mr. Salmon, himself, or, with the exception of Mr. Cooper, by any of the other gentlemen who have been engaged in deciding on that difference. It is indispensable, therefore, that I should commence by removing all obscurity in these respects. With this view, I shall exhibit, first, the ideas that are now, and have

long been held, respecting the morbid conditions constituting organic stricture of the rectum; secondly, the various points in which these ideas appear to me to be false; thirdly, the danger and impropriety of a mode of treatment which has been suggested by these false ideas; fourthly, the peculiar views which my investigations have led me to entertain, respecting the formation of organic stricture at the upper extremity of the rectum, the manner in which the morbid action subsequently extends upwards and downwards; the different kind of strictures produced by its extension in the latter direction; the sources of the false impressions communicated, when the finger is employed to examine these strictures; and the manner in which these strictures require to be treated. By proceeding in this natural and orderly manner, I expect to succeed in placing the whole subject in clearer, fuller, and much more useful points of view, than the peculiar nature of the plan of my work admitted.

First, then, with respect to the received ideas of the morbid conditions constituting organic, or permanent, stricture of the rectum, the nature of these ideas cannot be more fully, or fairly exhibited, than by the following extract from the work of the very latest writer on the subject:—"Permanent stricture of the rectum," says Mr. Herbert Mayo, "consists in a partial thickening of the sub-mucous coat of the bowel, and of the adjacent cellular texture, through which means a smooth ring is formed, generally from a third to half an inch in depth, which projects into, and narrows, the channel. Sometimes the thickening does not include the whole circle of the intestine, but a segment only. It is presumable, that this thickening results from chronic inflammation. The ordinary seat of stricture of the rectum is from two and a half to four inches from the orifice of the gut; but sometimes it occurs at a greater distance, at six to seven inches for example."—*Observations on Injuries and Diseases of the Rectum*, pp. 165-6. London, 1833.

Two questions naturally arise out of the statements contained in this extract. The first is, can we account for the occurrence of such morbid conditions by any peculiarity in either the structure or the function of the rectum? I should think not. On the contrary, as the disorganising process is known, and admitted to commence in the sub-mucous and cellular tissues of the intestine, it is only necessary to reflect, that these tissues form a very loose and delicate connexion between the mucous and the muscular coats of the bowel, in order to see that, when they become the seat of such a process, the inflammatory action should necessarily spread equally in all directions, and consequently cause uniform, not partial, thickening of the parietes of the gut. It may be contended, perhaps, that the folds of the mucous membrane of the rectum favour the production of such circular septa or projections as Mr. Mayo and other authors describe. But this is a supposition

which will not bear even a moment's examination; for, as the folds in question are almost wholly found in the longitudinal direction, it follows, that the septa, or projections, supposed to be thus formed, should not be found observing a circular, but a longitudinal, course; a course which no author has described them as taking. Hence it appears, that the mucous membrane cannot have anything to do with the production of such morbid growths; and it is perfectly obvious, that the peritoneal coat is quite out of the question. It only remains, therefore, to consider how far the action of the muscular coats of the rectum is capable of contributing to the formation of the morbid projections, or septa, under consideration. This brings me to a theory, which Mr. Salmon has advanced. After saying that he "merely contends for the existence of permanent stricture in the lower part of the rectum," and admitting that distinct, thickened, and shelf-like projections are exceedingly unusual in the two upper thirds of the rectum, he asserts, that "circular stricture will, from the redundancy of the circular fibres, be most commonly within reach of the finger." But, if this reasoning were correct, it should be equally applicable to a higher portion of the bowel, where the longitudinal fibres are known to predominate, and where, be it observed, he admits permanent stricture to be of such rare occurrence. Moreover, it is quite obvious that the only basis, on which this theory rests, is the supposition, that the longitudinal and the circular muscular fibres of the rectum act separately and independently of each other; a supposition, as perfectly original as it is untenable. For example, when these two muscular layers are compelled to relax by the descent of feces, who is it that would dream of these layers not acting simultaneously? Again, when these layers are in the act of expelling the feces, who is it that would dream of their not contracting together? Yet the only actions of these layers are relaxation and contraction. Away, then, goes Mr. Salmon's theory; and so will go, I have no doubt, every other that may hereafter be constructed with a similar view; for, although I have shown that the two orders of muscular fibres at the upper extremity of the rectum often combine to produce spasmodic, and eventually organic, stricture at that point, I can find no similar principle to account for the same order of fibres producing the disease lower down in the intestine. I repeat, therefore, that there is nothing observable in either the structure or the functions of the coats of this bowel, to explain the occurrence of such partial thickening of its walls, or of such morbid growth from its walls into its cavity, as are usually described by authors.

So much for the first question, which has arisen out of the statements contained in the extract which I have given from Mr. Mayo's work. But the second question which they

suggest, comes more home to, and at once grapples with, the subject in debate. It is simply this,—are the statements, just referred to, sustained by the evidence of pathological anatomy? In answer to this question, I have only to say, that the views, which I have advanced respecting the anatomy, physiology, and pathology of the coats of the rectum, induced me to attempt its solution, by examining carefully all the anatomical museums of this city. Two of these are extensive, and have been collecting for more than half a century; three of them, although necessarily smaller, contain a great variety of very valuable preparations; and I shall now state both the morbid changes I have not observed, and those which I have observed, in such specimens of organic stricture of the rectum, as these collections enabled me to examine.

Except at the upper extremity, I observed no partial thickening of the parietes of the intestines at one or more points, and leaving healthy spaces between them; nor anything like smooth rings, or segments of rings, of any depth, or projecting to any extent into, or narrowing, the cavity of the bowel. And as to the morbid changes which I have observed, they are easily described, and range themselves under the three following heads; first, thickening of the parietes and narrowing of the cavity, limited to a small portion, often but a few lines, of the upper extremity of the rectum; secondly, a greater degree of disorganisation at the same point, and extended, but with much less thickening of the parietes, and far less narrowing of the cavity, a short distance upwards into the sigmoid flexure, and downwards into the rectum; thirdly, a greater or less portion of the sigmoid flexure thickened and ulcerated, and all that great portion of the rectum above its pouch thickened in its parietes and contracted in its cavity. These are the only kinds of organic stricture of the rectum that I have found; and, of course, the only kinds of which I admit, or shall admit, the existence, until satisfactory evidence to the contrary is produced. The first of these may be termed *primary stricture*, because I have shown that it is the first formed, and produces the others. The last may be called *long stricture*, from its being often seen presenting appearances closely resembling those of the long cartilaginous stricture of the urethra. And the second may perhaps be fairly named *transition stricture*, as the parts are merely in the act of passing from the condition of a primary to that of a long stricture.

You have now before you all the facts and reasoning upon which I have adopted such peculiar views of organic stricture of the rectum; and you will perceive that the grand difference between Mr. Salmon and me, upon this part of our controversy, consists in my denying, that partial thickening, rings, segments of rings, or rings of any depth whatever, occur at any point below the upper extremity of the rectum; where, however, and let it be

clearly understood, I admit the existence of a septum, with an opening of greater or less diameter in its centre. But I feel that all the facts and all the reasoning, that I have brought to bear upon the subject, will be insufficient to convince many of your readers, particularly those who have not read my work, if I do not endeavour to remove one great and very natural obstacle to their conversion,—namely, the distinct feel of a ring, or a succession of rings, communicated on such occasions to the finger in examinations per anum. I shall endeavour to prove, therefore, that this feel, however distinct and imposing, is altogether deceptive. For this purpose, I shall consider the matter under two opposite but natural points of view. First, then, let me suppose, that such an examination per anum is made by a surgeon, who believes, as all have hitherto believed, that the rectum, in its natural state, communicates freely, and at all times, with the sigmoid flexure, and that the parietes of the rectum stand wide open and apart. He feels that the pouch of the intestine is so open that he can roll his finger freely about in it, and that, on pushing his finger higher up, in the direction of the bowel, its point enters a narrow opening, or ring. But what idea does he form of the nature of this ring? The most natural that can be—that it is formed by an opening in the centre of a septum, thrown across the cavity of the gut, which he supposes to be always in a dilated and open state. The feel communicated to his finger being too distinct and perfected to be doubted, and the partial circular thickening, which he has so often seen at different points of the urethra, are all circumstances which combine to fix him in this opinion. But let me now place the matter in a different point of view. It seems to be generally admitted that I have succeeded in establishing the following facts:—first, that the rectum is much more muscular, and endowed with a higher order of motific nervous influence, than any other portion of the alimentary canal, the oesophagus alone excepted; secondly, that, as an inevitable consequence of this organisation of the rectum, instead of being in a dilated state, and communicating freely, and at all times, with the sigmoid flexure, the whole of that great portion of the intestine, comprised between its upper extremity and its pouch, is so firmly contracted as to cut off all communication with the flexure, except for the few seconds that the alvine contents are in the act of passing from the latter into the former, and being expelled from the body; thirdly, that, in consequence of having the middle and posterior divisions of the levator ani muscles inserted into it, and at opposite points, the pouch of the rectum is constantly open and dilated. Such being the real state of the facts, we are enabled to arrive easily at the true view of the matter. Thus, even in the natural state, when the finger enters a narrow opening above and leading from the pouch and conveys the feel of enter-

ing a ring, we recollect that this opening is nothing more than that which is necessarily formed by the inferior extremity of the contracted portion of the intestine. Again; when the finger is pushed through this opening or ring, no matter to what height it may be urged, its point there receives a similar impression; because the parietes of that part of the bowel, immediately above the point of the finger, remain contracted, and, of course, convey the feel of a septum, with a narrow opening in its centre, thrown, as it were, across the cavity of the intestine. Thus we perceive, that the feel of a succession of rings or strictures, varying in number according to the manner in which the finger is introduced, may be communicated in examinations of even the healthy rectum. How much more imposing, therefore, must not this be in cases where the mucous and muscular coats of this bowel are morbidly thickened, particularly in those to which I have given the name of *long stricture*? So imposing, indeed, does this feel appear to have been in its nature, that, unless by its influence, it would be difficult to explain how such projecting ring-like strictures have happened to be spoken of as ordinary occurrences, without any attempt being made to establish their existence by the evidence of pathological anatomy. But, as I have already shown, that this, the only unerring evidence, is opposed to their existence, it is to be presumed that the influence of the sense of touch, which I have shown to be, in this instance, so very fallacious, will cease to sway the mind against the reception of views which appear to be as simple and natural as they are obviously well founded.

The practical bearing of the foregoing observations is very important. It is this:—to show the unscientific and dangerous nature of a practice, which has evidently been suggested by the erroneous notions, hitherto entertained respecting organic strictures of the rectum; and which consists in dividing such strictures as are within reach of the finger in the direction of the sacrum, and at other points of their circumference. This practice appears to have originated with Wiseman, and is recommended by Copeland, White, Sir Charles Bell, Calvert, Salmon, and Mayo. It is evident, also, from their works, that the object of these authors is to divide an annular septum, which they suppose to project from the wall into the cavity of the intestine. But, if any doubt be entertained on this point, it will quickly be removed by turning to page 334 of Sir Charles Bell's "Treatise on the Diseases of the Urethra, Vesica Urinaria, Prostate, and Rectum," where this distinguished surgeon will be found directing us "to notch the *membrane* in several places," and then adding, that "this will be more effectual, and attended with less hazard, than one deep cut across the *septum*." Is it not perfectly clear, then, that this is the wall of the rectum, and not a membranous septum traversing the cavity, that is divided in this

operation? If, as it is asserted, the operation enables us to introduce a bougie, which could not otherwise be introduced, is it not equally clear that it does so by enabling the instrument to lacerate the bowel? Will not the same cut, that divides the stricture, particularly if that cut be in the direction of the sacrum, also divide the hæmorrhoidal arteries and veins, and cause dangerous hæmorrhage? If my view and statements be correct, all these questions must be answered in the affirmative, and the operation itself declared to be both useless and highly dangerous. But it is not merely on these theoretical principles that this opinion may be entertained, for the following extract, which conveys a very favourable idea of the author's candour and accuracy of observation, will be sufficient to show that it is also supported by the results of experience.—"The division of a stricture of the rectum," says Mr. Mayo, "is not entirely free from risk of one description. I divided, in a woman, a stricture of the rectum situated within three inches of the anus. In this case, as in the preceding, the division was made in a direction towards the sacrum. The wound bled at the time, but not to an extent to make me apprehensive of its return. A few hours afterwards, however, very serious hæmorrhage supervened. This was arrested by the introduction of a pledget of lint, saturated with a strong styptic solution, which was applied to the divided stricture. But the patient had lost so much blood, that I thought it not improbable that I should be compelled to look for and tie the bleeding vessel on account of a return of hæmorrhage. Except, therefore, under peculiar circumstances, I am not disposed to recommend the division of a stricture. The operation is painful; it does not render the use of the bougie unnecessary; and it is liable to be attended with a considerable loss of blood."—(Observations on Injuries and Diseases of the Rectum, pp. 173–4.) This extract contains matter bearing too strongly on the subject to require further comment. I shall, therefore, pass on to the consideration of the best mode of treating organic stricture of the rectum, whether situated within reach of the finger or not.

In what I have called *long stricture*, the cavity of the rectum is uniformly narrowed, and its coats are thickened, from the upper extremity to the pouch of the intestine; but there is nothing even approaching to distinct, thickened, and shelf-like projections found in the interior of the bowel. In cases of this kind, it is obvious that the stricture must always be within reach of the finger; and that the most natural and efficacious plan of restoring the natural calibre and condition of the gut is, by gradual and cautious mechanical dilatation, and thus causing absorption of the new matter deposited between the coats of the intestine. Hitherto the bougie has been the instrument chiefly employed to effect this object; but it is subject to several weighty ob-

jections. It is too inflexible to follow the course of the rectum, or be introduced with safety to the necessary height; and experience shows that it cannot be retained long in the bowel without great inconvenience, if not pain, from its weight and the unnecessarily strong pressure which, as a solid body, it exerts on the sides of the gut. On the other hand, in a firm but flexible gum elastic tube, of a size proportioned to that of the stricture, sixteen inches in length, and open at both ends, we have an instrument free from all these objections; for, although hollow and comparatively lighter than the bougie, it exerts so much pressure as is necessary; and when introduced high enough to enter a short way into the sigmoid flexure of the colon, which should always be our object, it can be retained in that situation for several hours, and with very little inconvenience. This last advantage is one of the highest importance to the end which we have in view. I know the fact to be as I stated it; and it may be easily explained thus:—when the point of a bougie enters the sigmoid flexure, the instrument is grasped a little lower down by the upper annulus or entrance of the rectum, so as to prevent the escape of either flatus or fluid feces, with which, be it recollected, the whole of the colon is almost always distended in cases of stricture of the rectum. In other words, this state, instead of being relieved, is exasperated by the introduction of such a foreign body as the bougie, and the natural consequences are violent efforts at its expulsion; while, on the contrary, the introduction of a tube gives exit to the accumulated gaseous and liquid contents, and not only places the patient, but preserves him, in such a state of comparative ease, that he is scarcely sensible of inconvenience from the presence of the instrument.

We see, therefore, that we have only to proceed upon these principles, in order to be enabled to make a successful impression upon the long stricture of the rectum; and, *à fortiori*, upon the primary and the transition species.

I have now put you fully in possession of my general views, and the precise nature and practical bearing of the difference between Mr. Salmon and me, on the subject of organic stricture of the rectum; and, by having done so, have placed myself in a better position to meet Mr. Salmon's observations, and enter on a close analysis of the statements which Drs. Blundell and Ryan, and Messrs. Stanley and Cooper, have laid before the profession.

Commencing, then, with Mr. Salmon's observations, that gentleman accuses me of "equal candour and incaution" for proposing such terms for the decision of our difference. I thank the gentleman for his acknowledgment that my conduct has been so fair and straight-forward in this respect. But, when he speaks of my incaution, he will find that he has attempted to seize the laurel before he has obtained the victory. Again, in alluding

to my denial that distinct, thickened, and shelf-like projections do not exist lower down in the interior of the rectum than the upper extremity of the intestine; my opponent says,—"Dr. O'Beirne is but ill acquainted with those matters, else he would know that it is exceedingly unusual to find any other result in the two upper thirds of the rectum, how much soever it may be contracted, than a uniform thickening of its parietes, from deposition in the cellular tissue between the mucous and muscular coats, by reason of the longitudinal fibres preponderating at those points, while circular stricture will, from the redundancy of the circular fibres, be most commonly within reach of the finger." I have already exposed the weakness of the theory with which this passage concludes, and shall not now stop to notice the *courteous* terms with which it commences, but proceed to consider the several admissions it contains. So then, according to him, organic strictures, and, of course, shelf-like projections are exceedingly unusual in the two upper thirds of the rectum. This admission goes nearly the whole of the way towards acknowledging the correctness of my opinions. But Mr. Salmon is rather late in claiming an acquaintance with the fact itself, for so far from its being mentioned in either his work or in his lectures, he represents the matter very differently. Thus, at page 23 of his "Practical Essay on Stricture of the Rectum," he says,—“In the greater number of the cases which have fallen under my observation, the stricture has been situated between five and six inches from the anus,” that is to say, situated in the two upper thirds of the rectum, where he now denies their existence. He cannot but know, also, that he is directly at variance with all authors, myself alone excepted, when he admits that distinct, thickened, and shelf-like projections are so exceedingly unusual in the two upper thirds of the rectum. It is evident, therefore, that this opinion is of very recent date, and that it has been forced upon him by the facts and arguments that I have adduced, aided by the results of the close examination to which his morbid preparations have been submitted.

In fact, the admission which I have just considered, and which, it is obvious this controversy has extorted, is of such a nature that my opponent is necessarily obliged to go still farther, and to say, that he “merely contended for the existence of permanent stricture in the lower part of the rectum,” that is, at or very little above the top of the pouch of that intestine. But the context clearly shows, that he does not deny the existence of this kind of stricture at the upper extremity of the bowel, a point upon which we have not had any difference. It only remains, therefore, that I should show that organic stricture is never limited to any point within reach of the finger, in order to establish the whole of my views; and I expect to be enabled to do this by the

following analysis of the various reports which have been made upon the subject.

Doctor Blundell describes two preparations marked A and B. Commencing with his description of the first of these, and taking it, paragraph by paragraph, and comparing it with the descriptions of Dr. Ryan and Mr. Stanley, the following is the first paragraph to be examined:—

"In this preparation (A) there is a distinct annular contraction, as if produced by a pack-thread, drawn with moderate tightness round the bowel, closing in so much as to preclude the insertion of the little finger. This contraction is situated about two inches and a half above the outer verge of the anus, rather less than more, and is decidedly within reach of the fore finger, independently of the help which might be derived from urging." Mr. Stanley, under the head—"1. Specimen. From a female," informs us that the outer surface of the intestine presented a circular indentation of only one line in breadth, and to a depth sufficient to reduce the cavity of the bowel to about one-third of its natural size. Now, let me ask, are such appearances on the *external* surface of the bowel the natural consequence of *organic* stricture?—No: even my opponent admits that this form of the disease is produced by the deposition of new matter between the mucous and muscular coats; and that this new matter, instead of approximating, separates these coats from each other, and, consequently, *opposes* the formation of anything like an indentation on the external surface of the gut. It is certain, also, that we know of no instance in which organic stricture has been found, in any situation, so attenuated as to be scarcely one line in breadth. But Dr. Blundell's next paragraph supplies another objection to considering this preparation as one of organic stricture.

"Immediately above the stricture," says Dr. Blundell, "an incision has been made in the side of the rectum, the thickness of which is visible, and exceeds one-eighth of an inch, and the inner membrane, also exhibited, seems evidently in one part of it to be destroyed by ulceration, and in another, where it remains unbroken, its structure is changed, being *roughened and thickened*." From this description, it cannot be clearly collected that there was change of structure either *at* or *in* the point of contraction. Mr. Stanley only mentions it as being observed above the contraction. Dr. Ryan, however, describes "change of structure *in* and about the contraction." But, on the other hand, Mr. Cooper, in a letter to me, states, that the contraction is "evidently not the result of change of structure." In fact, it is evident that this point could not be ascertained by merely inspecting the free surface of the mucous membrane, and that the only way of deciding it, was to cut through the annular contraction, in order to see whether there

was any deposition of new matter in the loose tissue connecting the mucous and muscular coats. But this was not done; and if it had been, I have not the least doubt but that no such deposition would have been found, and that the annular contraction would have disappeared.

Upon the whole, it appears to me, that the appearances described by Doctors Blundell and Ryan, and Mr. Stanley, fully bear out Mr. B. Cooper in pronouncing this preparation to be one of spasmodic stricture, a variety of the disease upon which Mr. Salmon and I have not had any difference.

"In preparation B," says Dr. Blundell, "apparently the entire rectum, and part of the sigmoid flexure of the colon, together with the womb and vagina, throughout the greater part of its length (both *in situ* with respect to the rectum), are carefully exhibited. *In this preparation either the entire rectum, or certainly all except the upper portion, where it is continued into the sigmoid flexure of the colon, is exceedingly thickened, and so contracted throughout the whole of the thickened part, that the little finger, especially in the inferior portion of the rectum; could not be passed along it without some violence.* Where there has been most deposit, the coats of the bowel exceed in thickness three-fourths of an inch. Various sinuses run in various directions, one apparently opening into the vagina."

"The uterus and vagina, lying *in situ* upon the rectum, seem to mark distinctly that part of the rectum which is most contracted and thickened, and which, as described, is the inferior portion clearly within reach of the fore finger, which, indeed, on making an examination, must evidently bear upon it immediately on passing the anus." Mr. Stanley, under the head "2nd specimen.—From a male," is less accurate in his account of this preparation, but Dr. Ryan describes it very satisfactorily. "*One of these*" (specimens) says the latter, "*shows a considerable narrowing of the rectum below the sigmoid flexure through the whole extent of the intestine; the parietes are better than three-quarters of an inch in thickness, and the canal is so reduced as scarcely to admit the passage of the little finger through some parts of it.*" All these descriptions, however, are distinguished by one remarkable feature, namely, that not one of them contains even the slightest allusion to the existence of distinct, thickened, and shelf-like projections from the sides into the cavity of the rectum. Lastly, it is only necessary to bear this fact in mind, and to note those passages in the above statements which I have marked in italics, in order to see and be convinced, that Mr. Cooper is perfectly justified in considering this preparation to be a specimen of one of the three kinds of organic stricture of the rectum, which I have described in a note at p. 35 of my work, and to which I have given the name of long stricture.

So much for the material difference, which

Mr. Salmon supposes, most gratuitously to have existed between Dr. Blundell and Mr. Cooper. I have still, however, to advert to a third preparation, not adverted to by the former gentleman, but accurately described by Mr. Stanley, and briefly noticed by Dr. Ryan. It is thus described by Mr. Stanley. "3rd specimen from a male. The lower part of the rectum, to the extent of three inches and a half from the anus, is uniformly and considerably contracted. The mucous membrane is removed by ulceration from the whole of the contracted part of the intestine. Several fistulous passages extend from the ulcerated part of the bowel to the margin of the anus." Dr. Ryan notices it by saying, "in a third specimen there is a projecting irregular stricture, about an inch and a half in length." But I am either grossly deceived, or Mr. Stanley's description shows that this preparation was one of fistula in ano, not of organic stricture. Viewing it in this light, it is easy to see the cause of the contraction observed at the lower part of the rectum.

In this analysis I have proceeded upon facts, not opinions, and the results are as highly favourable to my views as they are unfavourable to Mr. Salmon's. But why has that gentleman confined himself to such evidence as the comparatively few preparations in his own possession are capable of affording, when I have offered him so wide a field as the great anatomical museums of London, for supporting his opinions? Such a mode of testing the correctness or incorrectness of my views on the subject, would have been perfectly conclusive; and I repeat, that I only wait to receive satisfactory proof of their unsoundness, in order publicly to renounce these views. Truth alone is my object, and I entertain no fear whatever of losing professional character by abjuring an error, entertained upon such seemingly strong and natural grounds.

Gentlemen, having concluded this part of my reply to Mr. Salmon, I trust that, as friends of science and advocates of free discussion, you will not be displeased if I reply also to some observations contained in a note which you have appended to Mr. Salmon's last communication. The note runs thus:—"Though we have given a most favourable opinion of Dr. O'Beirne's views on defecation, and still maintain that most of them will lead to the happiest result in the practice of medicine, yet we cannot agree with him on all points. We cannot assent to his doctrine, that the rectum is not a receptacle for the fæces, because we, and every one who has experience of the practice of obstetrics, have, during parturition, repeatedly detected feculent matter in the rectum, nay, the bowel is often impacted with it." I feel deeply grateful for the high opinion which you have expressed, and continue to entertain of my work; but I cannot assent to the proposition, that, in selecting the act of parturition for the purpose of showing that the rectum, in its natural state, does not permit the accumulation of fæces, you have chosen a fair ground

of objection. The act of parturition cannot, it is true, be called either a morbid or an unnatural condition of the woman, but it places the rectum in an abnormal state. In that act violent expulsive efforts are made, which are not made in health, except at stool, and even then with much less force. Now, it is obvious that the same violent efforts which are made to expel the infant, must act also with great force upon the upper annulus, or extremity of the contracted rectum, force open its cavity, and fill it with fæces. It is likewise obvious, that, as these efforts are repeated, and as the head of the infant, in the act of parturition, presses against the lower part of the rectum and opposes the discharge of fæcal matter per anum, the fæces so forced into the bowel must become impacted. It is clear, therefore, that the fact of the rectum being found filled and impacted with excrement, occurs under circumstances altogether peculiar to the act of parturition, and, consequently, under circumstances totally unconnected with, and inapplicable to, an exposition of the ordinary state of this bowel. Indeed, so natural does the occurrence in question seem in parturient women, that it would be, I am sure, much more frequently met with, if the generality of pregnant females, particularly those of a respectable class, were not known to attend to the state of their bowels, at least for some time previous to their accouchement.

I have the honour to be, Gentlemen,
Your very obedient, humble servant,
JAMES O'BEIRNE, M.D.

Foreign Medicine.

Researches upon the Development of the Class "Mammalia."

BY M. COSTE.

In a Paper read before the Academy of Sciences, Paris.

THE author commences by stating the difference of opinion of naturalists on this difficult question, and thinks that a sufficient number of facts, touching upon the ovum of the female, and of the mammiferous tribe, have not yet been accumulated in sufficient numbers to put an end to the uncertainty of inquirers into this subject. In the midst, however, of the contrary opinions which have been elicited, two stand prominent. The first considers the Graafian vesicles to be the same as the ovum of the mammiferous tribe; the second, on the contrary, supposes that the ovum is the small spherical body which these vesicles enclose. To resolve this important question, M. Coste

opened forty impregnated rabbits: the result of his observations leads him to suppose, that the small spherical bodies, contained in the Graafian vesicles, are the ova of the mammiferous tribe, and that these ova do not differ from those of birds. The vesicles of Graaf, says he, are not the ova of the mammalia, for they are much more voluminous than the ova which we meet with in the fallopian tubes; for example, in rabbits they are a line and a half in diameter, whilst the ova, found in the tubes, are about the sixth of a line only. On the other hand, if we look to what takes place in the ovary, two or three days after conception, we see that the number of Graafian vesicles, which has disappeared, is equal to that of the ova which have arrived in the fallopian tubes, but that, in the place which each of them occupied, their exterior membrane, torn in one point only, continues firm, to concur in the formation of the corpora lutea. This fact, which it is impossible to doubt, shows in a very evident manner, that it is not the Graafian vesicles which ought to be considered as the ovum of the mammalia, and that we must not, consequently, seek for the analogy with those of birds.

Ova of the Mammiferous Tribe.

There exists upon the internal surface of the proper envelope of the Graafian vesicles, a membrane, which is double in the whole of its extent, except in one point, where we find lodged a little spherical body, the sixth of a line in diameter: this is the true ovum of the mammalia; it is transparent, and composed in the following manner:—first, of an exterior envelope, which M. Coste speaks of under the name of vitelline, because, like the membrane which encloses the yolk of the egg in birds, it is in immediate contact with the cicatricula, and because it encloses the foetus and its appendages, without having any immediate connexion with them; secondly, the vitelline or membrane of the yolk, which encloses in its cavity a spherical mass, of a yellowish-grey colour, composed of globules and granules; this mass is evidently the yolk of the mammalia, for it is upon it that is placed what is analogous to the cicatricula or blastoderma. At the surface of the yolk, we remark a membranous covering, of a yellowish-grey colour, whose external surface is in contact with the internal surface of the membrane of

the yolk, and by its inner side with the whole extent of the surface of the yolk; this is a complete vesicle, in which the vitellus is enclosed; this disposition seems at first to exclude all comparison with the cicatricula of birds, since this last only appears on the surface of the yolk; but if we consider that the cicatricula of birds, some time after conception, becomes a complete vesicle, which encloses the vitellus, we shall then have no difficulty in finding an analogy with the vesicle which exists in the mammiferous tribe: this analogy appears more evident still, if we reflect that the omphalo meseraic vessels, which develop themselves in the germ of the mammalia, express in a faithful manner the disposition of the lateral vessels, which develop themselves in birds, and that the first traces of the embryo of mammalia appear in a point of the vesicle of the germ, formed by globules, which range themselves according to a methodical order on each side of a determinate or fixed axis, by means of the motions which produce the same phenomena in birds; the ova of the mammalia have then in the ovary, like that of birds, three parts, which it is necessary to follow in all the modifications, which conception determines.

1. The vitelline membrane, or membrane of the yolk.

2. The yolk.

3. The vesicle of the germ blastoderma, or cicatricula.

But the cicatricula of birds, whilst the ovum is yet fixed in the ovary, presents in the central part a little transparent vesicle, discovered by Purkinge, and which, he supposed, broke at the moment of conception. It becomes then necessary to know, if this vesicle exists equally in the mammiferous tribe. M. Coste inclined to the opinion, that animals of this class were deprived of it, until he by chance discovered, in opening an unimpregnated rabbit, upon the surface of the yolk, and in the substance even of the vesicle of the germ, a small, delicate, transparent vesicle, similar to a soap bubble. The existence of this appearance has been verified by MM. Laurent, Lauvillard, and Rousseau, who are perfectly satisfied as to the existence of a vesicle in the ova of rabbits. The author considers this fact as analogous to the vesicle of Purkinge in birds. He next passes to the examination of the first modifications which the ova undergo in their fall from the ovary. Two days

after conception they have penetrated into the oviduct, and are so similar to the small spherical bodies which the Graafian vesicles enclose, that it is impossible to doubt that they are, in truth, the ova of the mammiferous class of beings.

The membrane of the yolk, the vesicle of the germ, and the vitellus, or yolk, have not yet undergone any sensible change. Four days after conception, the ova have arrived at the cornua of the uterus, to the number of four or five in each, but have not yet any determined position. Like to a drop of water, or a bubble of air, they are free and moveable. At this time they are a line in diameter, and are visible to the naked eye. We recognise the vitelline membrane, and the vesicle of the germ; but the vitellus has not been absorbed in a manner proportionate to the growth of the vesicle of the germ. Five days after conception they have taken a fixed position, which they preserve during the whole period of gestation; they are placed in a constant line, from which they never deviate, and which corresponds to the insertion of the mesentery. They have not yet any other connexion with the uterus, besides mere contact; and now it requires a certain effort to detach them; they are always spherical, but now they are sensibly augmented in volume, being in diameter about two lines; the membrane of the yolk has acquired a bulk much greater than that of the vesicle of the germ, which it encloses, and which only occupies about a third or little more of its interior; it is connected by a point of its surface to the internal face of the membrane of the yolk, and in the place where this last is applied to the uterus; in the same part it presents a circular or elliptical spot, formed by globules, which are arranged according to a particular order, and which are placed at the external surface of the vesicles of the germ, and which is, in fact, the rudiment of the embryo.

From these remarks and experiments it appears, therefore—

1. That it is the small spherical body contained in the vesicle of Graaf, which is truly the ovum of the mammiferous tribe.

2. That this ovum is perfectly like that of birds.

The Bignonia Catalpa in Asthma.

Encouraged by the success which the Japanese physicians, Kæmpfer and Thumber,

have met with in the employment of the *bignonia catalpa* in different asthmatic affections, some of the medical men in Naples have made trial of the plant, and have obtained results equally satisfactory. By administering in the morning a decoction made of the seeds, and part of three or four of the husks of this plant, in twelve ounces of water boiled down to six, and a similar decoction in the evening, the fit of asthma is much diminished in violence. The following is the result of an analysis of this plant, made by Signor Grossi:—about ten parts of an oily substance; malic acid partly combined with lime, partly in a free state; and, lastly, an uncrystallisable sweet principle; from which it appears probable that the medical properties are situated in the oily portion.—*Bulletino delle Scienze Mediche, Bologna.*

Sense of hearing transmitted to the Brain by Cicatrices in the Cranium remaining after the Operation of Trepanning.

From observations made at the Hôtel des Invalides it would appear, that the ear is not the only channel for the transmission of sounds, since loud noises may be transmitted to the brain by any opening made in the walls of the cranium, and by the cicatrices which replace the loss of substance after such opening. After performing the operation of trepanning on some soldiers in the Hôtel des Invalides, M. Perier, the assistant-surgeon, noticed that the sensation of an accustomed and unconstant noise succeeded the operation; this symptom was the cause of the discovery of this phenomena, from which it is impossible, *à priori*, to deduce the consequences. In the presence of M. Savart, the following experiments have been performed several times by M. le Baron Larrey. The ears of persons operated on were hermetically closed; but, notwithstanding this, the perception of sounds was evident, especially if they were directed in a line perpendicular to the cicatrix. By this same channel, vocal sounds were perceived at different distances, and in such a manner as to render any collusion between the experimenter and the sick person impossible. The beating of a watch was also heard at some inches' distance; but, upon firmly placing the palm of the hand upon the cicatrix, the ear still remaining closed, even the loudest noise was not heard.

ON PERICARDITIS.

BY A CORRESPONDENT.

It appears that some remarks which I made in a former number of your Journal, relative to two cases of pericarditis occurring in the Middlesex Hospital, have been met by a reply, somewhat illogical, from a "Stethoscopist." The point, and I believe the only point, on which the writer and myself differ, is the cause of a particular sound heard in the region of the heart, in the acute stages of pericarditis.

In referring to my brief observations upon the disease, I find that I am not so much disposed to lay down the law as my adversary would let it be imagined; for, in words of the greatest humility, I say, "I am inclined to think it more than probable that the sound (I mean the peculiar rough sound) is caused by friction external to the heart itself, and that my impressions were strengthened by some cases which I had seen." It is strange, but no less true, that, in medical arguments, facts, brought forward by one man to support a theory, serve another man for one decidedly opposed to it: such is, unfortunately, the case in the present instance.

Your correspondent begins by relating a case recently in the hospital. The patient was affected with rheumatism, and pericarditis came on. He states, that while lying on her back two sounds were heard, the one a bellows sound, the other a rough grating sound. And he goes on accurately enough to say, that the former of these sounds only was heard when the patient laid on her side or sat up. Now, this certainly must, in the eyes of the unprejudiced reader, go to support my idea rather than that of my opponent. Here are two sounds, the one apparently from a cause within the heart, the other more resembling the sound heard in pericarditis when as yet we do not suspect disease of the internal membrane. But the writer is anxious to do more than state facts, for he argues upon what he is not certain of in the following words:—"On the 22nd day he could speak pretty accurately as to the condition of the membrane, viz., that it was partially adherent." I would ask him, how does he know that it was partially adherent? He has not evidence that it was so! morbid inspection did not declare it to be the fact, therefore all this goes for

nothing, and it is not too much to say, that it is false reasoning. The two sounds are quite sufficient for my point, and they are different sounds. The latter, which more particularly concerns me, goes away in particular positions. This does not militate against the idea of mamellated portions of lymph rubbing against one another, and giving rise to it. The lymph may be only in that spot where the reticulated surfaces would come into contact in one position of the patient, namely, on the back, or on the side, or when sitting up. Again; there may have been fluid in the pericardium; and the least change of posture, changing the situation of the fluid, might give rise to a morbid sound, or to no sound at all. But I must not insist upon this, since I have just found fault with your correspondent for building arguments merely upon supposition. At all events, it will be clearly seen that this case, which is triumphantly brought forward, if it does not support the doctrine of attrition, goes no way to disprove the truth of it.

The two cases I brought forward are said to be inappropriate; why so? In Scott, there was serum in the pericardium; but this very fact accounts for the peculiarity which is noted, namely, that the bruit was sometimes distinctly heard, at other times but faintly, and not in the same spot. Again; the sawing sound was heard at the base. The fluid which existed in the cavity may have prevented the rubbing together of the surfaces at the apex, but, not extending as far as the base, no impediment took place to the friction of the surfaces, therefore I conceive this case entirely bears me out. As to the second which I related, the writer labours under misapprehension. He seems to have entirely overlooked my observations (that the lining membrane is often a case of bruit, and often accompanying acute rheumatism) and thinks that I attribute all sound to attrition, thus distorting the statements which I made.

The second case, it will be seen, was related to illustrate the chronic form of pericarditis, and to show the value of the bruit—not to explain the cause.

In regard to the case which was successfully treated, I ventured to throw out a hint, that as the bruit was heard when the heart pulsed slowly, and disappeared when it acted forcibly, it might be because the obstacle which the lymph offered was overcome by the more powerful action. I am asked, why did

the excitement of the patient remove the sound? and why the heart, simultaneously with the disappearance of the sound, become accelerated? The excitement removed the sound in the same manner as it was removed when the heart acted forcibly; and I can offer no better explanation, than that the opposing lymph was more readily overcome; and, as to the second question, the heart may or may not have become accelerated; a change of position might affect the fluid (if it existed) in the pericardium, or the surfaces which gave the sound might cease from a very trifling cause to come into contact.

Your correspondent is surprised that the sound, if caused by attrition, should be between the sternum and nipple, as in this case, but I think, if his memory serves him, he will find that in the majority of instances it is so. I confess I cannot see the surprise, for a larger surface must come into contact at the base than at the apex.

Then it is doubted whether lymph could be firm enough to cause a rough sound. I need only appeal to any practical pathologist, who has seen lymph firm, mammellated, and thick, enveloping the heart, and lining the pericardium, for the possibility of a roughness being heard, where these surfaces meet one another in the action of the heart.

The various changes, which organised lymph undergoes, the secretion and absorption, which follow, are next alluded to. All these changes going on are so many arguments in favour of attrition. Who has not anxiously watched, day after day, a patient with pericarditis? Now, he has heard a sound, rough and grating; to-morrow it is lessened, and the next day it is gone. As the patient gets better it may return, and at length disappear, if there be perfect restoration of the part. And how is all this to be explained? When lymph exists, there may be attrition; when serum is poured out, it may be absent; when this is absorbed, the sound returns, and when the surface of the pericardium regains its natural state, there is no cause for the morbid sound.

The stethoscopist closes his remarks with the result of his investigations, and the burden of his song is, that the lining membrane of the heart is invariably the cause of the sounds heard in pericarditis. He thinks there must be inflammation internally if there be inflam-

mation externally. This I must decidedly differ from, while I am, at the same time, ready, nay, anxious, to admit there is often a corresponding action; but that some cases of inflammation of the pericardium, without corresponding disease of the lining membrane of the heart, and attended with a bruit, have taken place, and do take place, there can be little doubt. I would not bring forward examples in proof of this, but refer your readers to those published by Dr. Stokes, these are at once conclusive, and the authority not to be doubted.

That the lining membrane is very often affected, and after a few years proves the cause of fatal diseases, is a fact too memorable to need comment; but it is also true that pericarditis may be cured. And where it is cured, I would suggest that no disease had taken place within the heart, when inflammation was going on externally. We find not unfrequently, in post mortem examinations, the pericardium universally adherent, and the heart healthy, the patients having lived to an advanced age, and dying of disease elsewhere, and not connected with the heart.

The writer, with some gravity, asserts, that an inelastic and puckered state of the valves and internal lining of the heart produces a rough, grating sound. I find no necessity for this, since all are determined upon the point; but he cannot mean that the membrane is inelastic and puckered in acute pericarditis, therefore we must look to some other cause than the valves or lining membrane, to account for the bruit in acute inflammation of the pericardium.

I have now to apologise for taking up so much space in your valuable Journal, and to thank your correspondent for calling my attention again to this interesting though obscure disease, as I find he has strengthened me in the opinion which I ventured to assent to, that attrition of the surfaces of the pericardium, covered with hard, unequal, and mammellated projections of lymph, may give rise to more or less sound.

January 2nd, 1834.

M. GUERBOIS has been appointed to the office of surgeon of the Hôpital de la Charité, vacant by the death of M. Boyer.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, January 25th, 1834.

MR. PETTIGREW in the Chair.

Some Peculiar Forms of Venereal Sore.

THE minutes of the last meeting having been read and confirmed, and the instruments mentioned by Mr. Waite exhibited to the Society,

Mr. Hunt rose to mention the following case:—a gentleman had severe symptoms of gonorrhoea, with pain beneath the frænum; leeches were applied by the surgeon who attended him at the time, and each bite formed a separate ulcer, which spread rapidly; the opinion of Mr. Hunt was then taken, and as he did not think it was a case of gonorrhoea, mercury was prescribed, and chloride of soda injection used; this treatment was rapidly successful. Another case similar to the former had also fallen under his observation, and his experience led him to think that this was a form of syphilis simulating gonorrhoea, but easily yielding to moderate doses of mercury.

Mr. Johnson had seen three cases of the same kind, and perfectly agreed with the last speaker as to their syphilitic nature, and the appropriateness of using mercury.

Some further remarks upon this form having fallen from one or two other members,

Mr. Johnson read the promised paper on some peculiar forms of venereal sores. The particular kind of ulceration, to which he wished to call the attention of the Society, is generally situated on the inner prepuce; sometimes it is complicated with gonorrhoea, but generally is independent of this complaint. It appears at first as a vesicle, increases in size, and acquires the size of a split pea, bursts, then ulcerates, and afterwards forms granulations. In the cases which he had seen, there were many ulcerations present at the same time, in different states of progress; it is highly infectious, and is occasionally accompanied by eruptions of various kinds.

Several cases, illustrative of this new form, were then mentioned, and some judicious remarks upon the treatment made. In the first stage, which is one of inflammation, antiphlogistic remedies, calomel, senna, &c., are neces-

sary; afterwards when the granulations have made their appearance, a modified plan of treatment is required, but a moderate course of mercury seems absolutely necessary for the cure. Another form of ulceration, or excoriation which appeared shortly after connexion, had fallen under his observation, and had like the former yielded to a slight mercurial treatment.

Mr. Hunt said that the affection, so well described by Mr. Johnson, was not of recent observation, for he had met with several cases of the same kind seventeen or eighteen years ago; he had found that the ulceration commenced in a minute vesicle, which was filled with clear fluid; this became slightly turbid on the second day, and at the end of the third contained a purulent secretion. Febrile symptoms accompanied this form of sore, and it was found to occur in persons who had irritable urethras, and to follow the introduction of a bougie; he did not think that it was of a syphilitic nature, and the result of the cases, which he had seen, seemed to prove the truth of his opinion.

Mr. Wade had met with sores similar to those which were now the subject of discussion. After describing these ulcerations, he stated that he had found small doses of blue pill of service; he did not think it characteristic of the complaint that there should be a number of ulcers.

Mr. Greenwood made some remarks on the subject, but from the rapidity of his enunciation, we could not clearly comprehend the purport of his speech.

Mr. —, house surgeon to the Lock Hospital, rose to confirm the observations of Mr. Johnson; many of the patients, in whom Mr. Johnson had observed this ulceration, had afterwards been seen by him, and he had found the symptoms perfectly to agree with those described.

Mr. Johnson, in conclusion, said that the sores mentioned by Mr. Hunt and Mr. Wade were evidently of quite a different nature to those which he had seen, and of which no description had to his knowledge hitherto been given.

Notice was then given, that Mr. Costello would, on the next evening, bring forward the subject of torsion of the arteries, after which the meeting separated.

MEDICAL SOCIETY OF LONDON.

Monday, January 27, 1834.

W. KINEDON, Esq., President, in the Chair.

Perforation and Disease of the Stomach.

THE minutes of the meeting were read, when

Mr. Moore stated, that the contents of the stomach, in the case mentioned by him at the last meeting of the Society, had been examined, and that acid (oxalic, if we understood rightly) had been found in them.

Mr. Leeson said, that, on the 19th of last month, in the evening, a female, æt. 16, was seized with vomiting, violent pain in the stomach, and headach; and he found, on calling next morning, that she was dead. An examination of the body was made, when two openings were found penetrating through the coats of the stomach, which were, in some other places, much attenuated. No other morbid appearances in the abdominal cavities were discovered. The fluid was not submitted to any examination. In answer to a question, he said that the blood coagulated and was not arterialised.

Mr. Proctor considered that the stomach might still go on performing its functions for a considerable period, even though extensively diseased. In confirmation of this opinion, he related the case of a gentleman who was accustomed to indulge freely in the pleasures of the table, and who had two severe attacks of vomiting, at intervals of several months. The opinion of many of the most eminent practitioners was taken, which was, that the pyloric orifice was in a state of disease. At length the patient died, and the stomach, with the exception of a small portion near the pyloric valve, was found one mass of disease.

A spirited discussion upon the subject of damaged grain followed, after which the Society separated.

MEETING AT THE ROYAL COLLEGE OF PHYSICIANS.

On Monday evening, Jan. 27th, the President and Members of the Royal College of Physicians held their first meeting, for this year, in the library. There was a crowded

assemblage of medical and other scientific individuals. Among the distinguished visitors who sat on the right and left of Sir Henry Hallford, were Earl Grey, Lord Althorp, the Marquis of Lansdowne, Lord Melbourne, Lord Duncannon, the Lords Chief Justices of the King's Bench and Common Pleas, the Vice Chancellor, Bishops of London and Llandaff, Judge Alderson, Mr. Ellice, &c., &c.

Sir Henry then read a paper on the education and moral conduct of a physician, in which he forcibly illustrated the importance of classical and general education to medical students, he pronounced a high eulogium on the ancient classic writers; lauded the universities of Oxford and Cambridge as seminaries of learning; showed the value of a religious and moral education to the cultivators of medicine; commented upon the elementary branches of the healing art, and clearly demonstrated the necessity of studying all of them. He admitted that the English universities were inadequate for a medical education, and that the deficiency was supplied by students resorting to the schools of London, or to foreign universities. Harvey, Mead, Linacre, Sir George Baker, &c., were foreign graduates. He eloquently described the necessity of cultivating medical ethics, or the precepts for professional conduct, and alluded to the oath of Hippocrates, which enforced caution, chastity, and honour, as the leading virtues of a physician.

He concluded his paper with an eulogium on the late Chancellor of Oxford, Lord Grenville, during whose administration, the Hunterian museum was purchased by the government, and for which the profession would be grateful to the latest times. He observed that the noble lord was then associated with the illustrious statesmen (bowing to Earl Grey and the other ministers) who managed the affairs of this great country at present.

The paper was a classic, elegant, production, well read, and heard with profound attention. It did not contain the slightest allusion to Medical Reform, and was calculated to impress the Ministers with the idea that the College of Physicians was immaculate. They, of course, were not aware of the fact, that foreign graduates or British graduates, except those of the two universities, were not admitted into the College, and that the medical education of the London schools would not be acknowledged by the institution.

**MEDICO-BOTANICAL SOCIETY OF
LONDON.**

Tuesday, January, 28, 1834.

DR. CROWNE in the Chair.

MR. GUTHRIE, President of the Royal College of Surgeons, was admitted an honorary fellow of the Society.

Dr. Sigmond then read two papers on a species of lilac of the West Indies, transmitted by **M. Ricord**, the other, on hydrophobia, by a Polish Physician.

**LONDON MEDICAL ASSOCIATION,
WESTMINSTER DISPENSARY, GERRARD-STREET,
SOHO.**

Tuesday, Jan. 28, 1834.

DR. RYAN in the Chair.

*Spontaneous Evolution.—Vascularity of the
Teeth.*

MR. THURNHAM related a case of spontaneous evolution at the seventh month of utero gestation, in which the fetus was expelled perfectly doubled.

Mr. Peacock then read the following essay:—The subject of this paper is one on which great difference of opinion has prevailed between some of the first names of our profession, the one party contending for the possession of vitality and vascularity by the bony substance, while the other denied to it vascularity, but believed in a certain degree of vitality. What, however, vitality can be in the absence of vascularity I am at a loss to conceive. The latter, at the time of the publication of the natural history of the teeth, appears to have been the opinion of **John Hunter**; but in the diseases of the teeth, which he wrote subsequently, we find him adopting the belief that the teeth are similar in organisation to the bones, and subject to similar diseases. In this opinion he has been followed by **Fox**; and **Bell**, in his late work, has ably defended the vascular endowments of the teeth. In France, **Meckel** and **Serres** have supported the doctrine of their vascularity; and **Duval** has even gone so far as to suppose them possessed, under certain circumstances, of the power of repairing injuries.

The arguments against a circulation existing in the teeth are drawn from their apparent

insensibility; their showing no vessels when the attempt is made to inject them in the ordinary way, and their remaining unchanged in states of system which affect the rest of the skeleton.

It has been said that they are not sensible; and as, without sensibility, we cannot conceive vascularity to exist, so we cannot believe them to be vascular. The power, which we possess of detecting the most minute atoms of any substance in contact with the teeth, has been considered as the result of a mechanism, similar to that of the foot of the horse and some other animals, and which is so beautifully displayed by **John Hunter's** preparation in the College museum. In this animal, the nerves of sensation are observed, on approaching the superior aspects of the hoof, to be divided into fasciculi, of numerous and delicate fibrille, to which the impressions, made on the insensible hoof, are conveyed by its vibrations, and through them transmitted to the sensorium. The nerves of the lining membrane of the tooth have been viewed as performing the same office as these fibrille; and the bony substance, while it presents a hard body for mastication, has been also believed to convey vibrations to the membrane. Without, however, wishing to invalidate the analogy here presented, it does not appear to oppose the notion of sensibility to a certain extent being also possessed by the bony substance of the tooth itself.

It must have occurred to every one who is accustomed to operate on the teeth, that, if the teeth be supported, so as to prevent a jar being conveyed to the socket, a file may be applied, with considerable force, to the enamel without anything which could be considered painful being induced, but so soon as the enamel has been removed, and the instrument comes down to the bone, the patient makes a sudden start, sufficiently evincing the difference of sensibility between the two structures. So also in scaling what are termed pitted teeth; no pain is complained of so long as the instrument is in contact with the enamel, but the slightest pressure on the uncovered parts can often not be endured. How, then, is this? did this sensibility depend on vibrations, conveyed through the bone to the lining membrane of the tooth, could we expect to find such difference in our perception of impressions, made on the surface of the enamel, only

two or three lines thick, and that of the bone beneath it? when, too, the fibres of the enamel are arranged in the very form best calculated to convey those impressions unimpaired. But we have yet stronger proofs that the bony substance is possessed of sensibility, for in disease we occasionally find it becoming so acutely susceptible, that the slightest touch causes a paroxysm of intense suffering. This I have several times observed in the denuded necks of teeth.

If, then, these considerations be sufficient to overthrow the idea of their want of sensibility, it may be right to proceed to the examination of the belief as to their vascularity.

Teeth cannot be rendered vascular by ordinary means of injection. This, however, we can scarcely deduce as an argument against their vascularity, since the same circumstance is observed in other parts of the system, the circulation through which is never denied. A more cogent objection is that resulting from John Hunter's experiments: from these it appears that young pigs, fed on madder, had their bones, and such parts of their teeth as were in course of formation, tinged red; but such parts as were already formed retained their natural hue. He further observed, that if, after discontinuing the madder for some time, the animal was killed, the bones were found of their usual colour, while the tinged teeth remained unchanged. If, however, we take into consideration the slowness with which it is admitted by Mr. Hunter the red colour was removed from the bones, and the less activity of circulation which the teeth must be allowed to possess, we can scarcely feel surprised at these circumstances, unless the animal had been allowed to live a very considerable time before it was destroyed.

The teeth, however, like several other parts of the system, present actual signs of vascularity only in states of disease. It is stated by Mr. Bell, that he has seen a clot of blood in the bony substance of the tooth; and it is well known that the teeth of those dying of cholera, and under other circumstances where an extremely congested state of the lungs exists, have their teeth in parts highly discoloured with blood. This discolouration, on breaking the tooth, is found not to be gradually extended from the circumference towards the centre, but to be disposed between

laminae of the bone, and to have an untinged layer between it and the surface.

It has been argued that the bony substance is not found to be changed in those diseases, which cause an absorption or increased deposition of the calcareous matter; but, though I am not able to say whether, in mollities, all the teeth are ever affected, their pearly whiteness in phthisis, and dulness in old age, are familiar to all.

With respect to the want of analogy between the mode of formation of the teeth and that of bone, I would contend that the existence of a perfect analogy is not necessary to the belief of their vascularity.

The osseous structure of the teeth must be supplied with such circulation and vital endowment as is consistent with the function which it has to perform, and the situation which it occupies in the system.

Teeth, subjected to maceration in weak acid, have their triple phosphates dissolved, and a cartilaginous matrix remains, corresponding to the size and shape of the bony substance of the tooth, being in this respect precisely similar to bone. Of the enamel I have never been able to obtain the animal portion, but during solution very dilute flocculi, apparently of a membranous nature, are observed to float in the fluid. The dark colour of the teeth of the lower animals is owing to a membrane covering it, which, during solution, separates in the form of small shreds. I am also inclined to believe that the yellow colouring which appears on the surface of some teeth, extending from the neck to the opposing surfaces, is also a membranous growth.

If the opinion which has been above supported be correct, it must necessarily lead to the abandonment of the ideas common till the time of Fox, and still to be met with in many of our professional writings, that caries is a mere mechanical corrosion from stagnation of saliva in a state of putrefaction, and other irritating substances. Caries is stated by Mr. Bell to commence at the periphery of the bony substance, at its point of connexion with the enamel, and thence to extend inwards towards the central cavity. The discoloration of the enamel he considers the effects of disarrangement of the perpendicular fibres of the enamel, from loss of support in the bony substance; and it is to his work that we owe our most luminous views of almost every point connected with the

Caries would appear to be the result of a diseased action dependent on a local or general cause, and acting upon an originally faulty organisation. Without the belief of an action taking place in the tooth itself, it would not seem easy to account for the softening, often found extending deep into the substance of a tooth, though, perhaps, the only external sign of this disease is afforded by a minute discoloration of the enamel, and no opening existing. And without the supposition of an hereditary predisposition to decay being called into action, we should have difficulty in explaining the healthiness of teeth in some families and individuals, and their proneness to decay in others, and the frequency of teeth being found similarly decayed which are in course of formation at the same time. Caries has been supposed precisely similar to the decay of pivoted or artificial teeth, but a little observation will show a decided difference between them. In caries, a dark line, marking the progress of the disease, will be observed extending from some point directly beneath the enamel to the central cavity. The decay of artificial teeth will be found to originate in any part of the bone exposed, and to spread equally in all directions, unless some obvious cause to the contrary exists.

The function of the lining membrane would appear to be to form the teeth, and advance them to a state of perfection; that of the periosteum of the external surface to maintain these organs in a state of vigour. Without this belief, it would not, I conceive, be very easy to explain the objection urged by John Hunter, that, long before the milk-teeth are shed, their nutrial vessels have been absorbed, though the teeth still appear perfectly healthy; and the circumstance of the frequency of ossification of the foramen, leading to the central cavity, taking place in persons of mature age, without the teeth seeming to suffer.

With respect to the milk-teeth, their nutrial vessels would seem to exist no longer than they are required for the growth of the tooth; when this end has been attained they become obliterated, and the tooth is then dependent on its periosteum alone for support, till, after the fangs have been absorbed to allow the permanent tooth to pass forward, it is at length shed. A similar function—that of nourishing the teeth after their nutrial vessels derived from the fangs have been obliterated—would

seem to be performed by the periosteum of the permanent teeth.

An interesting discussion took place, in which Mr. Thurnham, Mr. Davies, Mr. Crutch, and others, took a part.

THE
London Medical & Surgical Journal
Saturday, February 1, 1834.

**POLICY OF THE COLLEGE OF PHYSICIANS.—POLITICAL INFLUENCE.
—ILLEGALITY OF EDINBURGH DEGREES.**

THE first Meeting of the College of Physicians did not disappoint our expectations. The sketch, which we gave last week by anticipation, was so far correct in the outline, that, now that the event has become historical, we have little else to do than to fill in a few details, to convey a correct impression of the reality. The concourse of visitors was as great, and as varied, as we remember to have seen on any former occasion at Pall Mall East. Of course, the attendance of the Members of the Corporation was numerous; the Licentiates, who had been politely honoured with an invitation by the Presidents and Fellows, were many of them present; and among the unprofessional visitors we noticed, in addition to some of his Majesty's Ministers, several of the most distinguished persons at present in town. It has always been the dexterous policy of the learned President, to surround himself, on these occasions, with persons of high official rank in the state, without any regard to the mutations of politics; and, in this, we admire the versatility of his powers, and the depth of his genius. Whilst their presence illustrates the meetings of the Corporation, in a manner unknown to the other scientific bodies of the kingdom, it helps to impress upon the public an opinion of the influence of the learned President in the highest quarters, which is essentially serviceable to the

College at the present time, when the Corporation is, as it were, committed with the profession, and both are appealing to the powers of the state. Whether this influence, or supposed influence, will prevail against the appeal of the great body of practitioners to the Legislature, is a question, to one side of which we are too deeply pledged, heart and soul, to give an unbiassed opinion; but of this we are certain, that, should it prevail, it is all up with Medical Reform.

The learned President's address upon the education and duties of a physician deserves the praise of an elegant and classical composition, and was worthy of his reputation as an accomplished scholar. It never has been our desire to underrate the value of classical acquirements to a physician, and their influence in forming his character as a gentleman; but we cannot allow the pretence of their possession, under the colour of an academical degree, to supersede the far more important acquisition of professional knowledge, or to give any title, by preference, to the honours of the profession. We have not the slightest apprehension, that the race of scholars will become extinct among physicians if the privileges of the Universities were abolished to-morrow. Classical literature has become of less professional importance in our days, since Latin has ceased to be the language of the learned; and the modern student of medicine has little occasion to go beyond his native tongue, and perhaps one or two living languages, for his treasures of knowledge. In the nature of things, therefore, it is absurd to exact a knowledge of the learned languages generally, or to any extent—nor is such an attempt made. Even Oxford, by her late regulations, allows the candidates for her degree in medicine to be examined in English. At the same time, some knowledge of Greek and Latin is

indispensable, in order to have a thorough understanding of the language of medical science, which is constructed on their basis, and of which a full apprehension is as essential to the medical student as the explanation of his symbols to the algebraist.

But, in the higher uses of classics, as refining the taste and enlightening the understanding, we must leave their study and cultivation to the abilities and leisure of individuals; and we may rest assured, that medicine will not be without its share of scholars, as long as it holds out a sufficient inducement to men of talents to enter the profession. In the learned President's exclusive care of the *liberal* education of a physician, an eulogy upon the English Universities can scarcely be considered a digression; although, in an essay upon *professional* education, nothing further perhaps would be said about them, (and that by way of note,) than that they claimed, by virtue of their prerogative as chartered seminaries of instruction, the singular power of conferring medical degrees without possessing a school of medicine. The continuance of this privilege was, no doubt, included in the learned President's filial prayer of perpetuity for the Universities. And we may learn to estimate, from his admiration of these bodies, how great a sacrifice of principle he was compelled to make by stern necessity, in sinking their Graduates in Medicine to the rank of Licentiates in the proposed alteration of the College by-laws; if, indeed, such a change has ever been seriously thought of, or has even met with his sanction.

Of the authenticity of the rumoured statement relative to these alterations, we expressed some doubts last week. Whether it was the admitted desertion of a principle hitherto adhered to with such pertinacity, or the bare-faced attempt to foist such a change upon the Licentiates.

in satisfaction of their claims,—both considerations induced us to pause and be incredulous. Another week leaves the rumour unvaried and uncontradicted; and, although the learned President carefully abstained from any allusion to the state of the profession, we are disposed to believe there is some truth in the report. We admired Sir Henry's eloquent recognition of the services of a former ministry in purchasing the Museum in Lincoln's-Inn-Fields; it conveyed a delicate hint, that his Majesty's present advisers have a glorious opportunity, as unquestionably they have, of earning the everlasting gratitude of the profession. But is it possible he could dream of inducing them to sanction such an alteration, as grateful to the profession, and the *ne plus ultra* of reform! The Fellowship of the College, though at present limited—unjustifiably limited—to English Graduates, is in some measure open. Every English Graduate has a *right* to the Fellowship. Under the rumoured by-law, the English Graduate is to lose this right, and to be sunk to a Licentiate. Degraded as the Licentiates are, they disdain the ignoble honour of seeing others reduced into their ranks, as a mean substitute for that elevation to which they claim themselves to be entitled. Unworthy as the preference shown to Graduates has been, the jealous distinction has not stifled all feelings of honour, nor will its abolition render the Licentiates insensible to the disgrace of submitting to a self-elective body, and permitting it to exercise its angry feelings, in awarding the dignity of professional rank to men of independence and talent. This would, indeed, be *too bad!* The very proposal of such a scheme of monopoly and misgovernment, in the midst of the changes our civil institutions are about to undergo, for the purpose of purifying them from evils of a like character, shown

to demonstration how unfitted men become, by the long possession of power, to estimate the wants and demands of those over whom they have exercised their oligarchical privileges. It is impossible such men will ever submit to condemn themselves.

Although the cause of Medical Reform cannot be seriously affected by the perverse activity of the College, in propping up its favourite system of exclusion; this specimen of what it would do will, we hope, animate the zeal of the true friends of the cause with increased spirit. They see what they are to expect from the justice and generosity of the College in the little spot of the republic of medicine, to which its legislative influence extends. In fact, the College has but little power for good or evil. The changes which are called for are beyond its reach. Its own limited circle of seven miles, within which it has even failed to support its privileges and laws, because they are repugnant to the sense of the public,—its little circle, we repeat, must be spread over the whole kingdom. Its sounding title must be made to correspond with the fact,—instead of being a little coterie of physicians practising amongst the fashionables of London, it must embrace the respectable practitioners of medicine throughout the whole of England. It must be *their* Corporation. Were the alterations, now proposed, in actual operation for the last century, they would not affect the case of the general practitioners against the College in its essential merits.

A pamphlet* has lately appeared, which places the necessity of a Parliamentary inquiry into the state of the profession in a startling position. We will not enter into the local politics of the Edinburgh

* An Examination into the Causes of the declining Reputation of the Medical Faculty of the University of Edinburgh, &c.

28 *Petition of the Physicians of London against the College of Physicians.*

University, or the quarrels between its public professors and its private lecturers, further than to observe, that they afford additional proof of the unsatisfactory condition of the profession in all parts of the United Kingdom. But we beg to impress upon the attention of the Graduates of that University the following alarming paragraph:—"The Professors of the University of Edinburgh are well aware that they have been granting medical degrees without any legal authority. If these degrees were questioned in a Court of Law, particularly in England or Ireland, there cannot be the least doubt it would be found that they are not worth one farthing, and could not be sustained."

It is not necessary, at present, to inquire into the correctness of this opinion;—it is sufficient for us that it is very generally entertained. It adds one item the more to the mass of grievances of which the profession has to complain to the Legislature. The profession is governed by self-elected, self-interested bodies: it has no connexion with its natural corporations: it is divided into jealous factions; and its legal constitution is founded on such anomalous contradictory charters and statutes, that it is difficult to say what are its legal rights.

RESIGNATION OF MR. LYNN.

THE venerable and eminent Mr. Lynn, the senior surgeon of the Westminster Hospital, resigned on Tuesday last, and has been appointed consulting surgeon. His place will not be filled up, as there was an understanding that three physicians, and three surgeon were adequate to the duties of the hospital, and consequently there will be no election for the office of surgeon or assistant-surgeon.

PETITION OF THE PHYSICIANS OF LONDON AGAINST THE COLLEGE IN PALI, MALL EAST.

PETITIONS are being signed by the independent Licentiates, against the Royal Col-

lege of Physicians, asking for a Parliamentary committee, and against a Royal Commission. The graduates of medicine, practising in London and throughout the country, should follow this example, while the general practitioners must not forget their own rights. Petitions should be forwarded from all parts of the United Kingdom, and as speedily as possible, as the monopolists are incessant in their exertions to prevent reform in any degree. They are using every kind of intrigue in misleading the government; but Lord Howick is too enlightened a statesman to be imposed upon by a few interested individuals, when the rest of the profession, the multitude, demand reform and redress of their grievances.

French Hospital Reports.

HÔTEL DIEU.

Colica Pictorum—Employment of Sulphate of Morphine in large doses.—Cure.

A MAN was admitted into the Hôtel Dieu with all the symptoms of painter's colic. For the first five days he was submitted to the treatment ordinarily used in La Charité; at the end of that time, the symptoms and the abdominal pains were just as violent as on the day of his admission. Two grains of the sulphate of morphine were given to him, and continued till evident symptoms of its narcotic effects were produced, and then all the symptoms vanished. This remedy, to which recourse has always been had in this hospital in cases of this nature, has generally been attended with success.

Two Cases of Lithotomy—Employment of the Instruments of M. Jacobson.

The first of these patients has been operated on several times; he is a man whose bladder is very irritable, and in whom each use of the instruments occasions a violent catarrhus vesicæ, which renders the cure tardy. At the last introduction, on Thursday, a fragment was seized and crushed; another was taken hold off, but a violent desire, on the part of the patient, to make water rendered it necessary to wait; the instrument was withdrawn; soon after which another small fragment passed into the urethra, and was extracted. Since the last operation the catarrh has been less violent, and M

Sanson has sanguine hopes of entirely ridding this patient of the stone in a few days.

The second patient is a woman, æt. 27; at the first operation a large soft stone was encountered, and broken without difficulty. The fragments remained in the bladder, but the irritable state of this viscus prevented the renewal of the operation; at the last report, however, the woman had passed some, if not all, of the debris.

HÔPITAL DE LA PITIE.

Cancer of the Right Kidney—Presence of Cancerous Matter in the Vena Cava, and in the Pelvis of the Kidney.

This patient entered the hospital with nephritis and disorder of the liver; the face was pallid; he had œdema of the legs, thighs, and scrotum; ascites; violent dyspnoea; scanty urine; and pain in the kidneys: he was treated for hypertrophy of the heart, which was clearly indicated by the stethoscope and by percussion, but died 18 days after entering the hospital.

Autopsy.—The heart was found much enlarged; each lung contained small kernels of encephaloid matter, and in the mesentery some of the lymphatic ganglia were found in a cancerous state; below the pillars of the diaphragm there was found a hard tumour, six inches long and two and a half broad, resting on the aorta, and containing, in its interior, the vena cava and right kidney, on the inside it was impossible to recognise any structure, for its tissue was replaced by a soft brain-like substance; this was more apparent at the upper than the lower part, where some traces of the original structure of the kidney were still left; the emulgent vein and vena cava, as far as the liver, were distended with this encephaloid matter, but the arteries were free; the pelvis and the calices were filled with the same matter; the left kidney was in a state of hypertrophy, and the liver was also enormously large. None of the other organs offered any thing remarkable.

Amputation of the Penis by a New Process.

M. Poirson, Chief Surgeon of Gros Caillou, has lately amputated the penis by a new process; he first introduced a soft flexible sound, some inches longer than the ordinary ones, into the bladder, and, having directed an as-

sistant to place one hand on the penis, close to the pubis, and to hold the loose end of the bougie and penis in his left, divided, with a small amputating knife, both the penis and bougie. M. Poirson states, that the introduction of the instrument facilitates the operation, and renders the search for the arteries more easy.

HOTEL DIEU DE TROYES.

Fungus of the Bladder.

AN emaciated old man, æt. 80, named Hubert Leon, was admitted for disease of the bladder and incontinence of urine, which was sometimes tinged with blood. He refused all medicines, and would not even submit to the introduction of a sound; after being in the hospital three weeks he died. The walls of the bladder were very much thickened, and although it was in an empty state, still it appeared above the border of the symphysis pubis; the cause of this unusual size was a large cancerous looking fungus, nearly filling up the whole of its cavity, and attached to its superior and anterior surface by a peduncle which appeared to arise from the mucous membrane; its surface was coated over with an orange coloured urinary sediment, and its interior appeared to be formed of a white pulpy substance, something resembling the structure of the brain.

Italian Hospital Reports.

Strangulated Hernia, cured by the effort of Nature.

BY C. BOZETTI.

THIS is a case which, without being so rare and curious as the relater supposes, still possesses considerable interest. A woman, ætat. 40, had hernia in the right groin, caused by lifting a heavy weight, it became strangulated, and as the practitioner, under whose care the woman was, did not recognise the complaint, no operation was performed; on the 9th day the tumour burst, and a great quantity of pus and fæces escaped. Signor Bozetti then saw the woman, when he recognised a portion of gangrenous intestine, which he imagined to be the cæcum, for he did not find any hernial sac; he brought the edges of the wound together, and in six days the granulations were already formed; in a month's time the fistula was reduced to a narrow opening, and two

months afterwards the cicatrisation was complete, and the woman was reported well.

Efficacy of Antimonial Powder in Neuralgia of the Face.

A painter of Catania was seized on the 5th of March, 1833, with a violent pain in the sub-orbital region of the left side of the face, preceded by vomiting and shiverings; the pulse, during the paroxysms of pain, was small, and the skin dry and rather hot; he had a sensation of general uneasiness, which diminished during the night, and at this time the pain in the face also abated a little. In the morning, however, the pains returned with renewed violence, and thus he continued till near the end of March, at which time his health became greatly disordered. Dr. Filippo Libra, having convinced himself of the nature of the complaint, prescribed sulphate of quinine, but this was continued for some time without the slightest amelioration. Opium, bleedings, purgatives, blisters, &c. were used in vain. Seeing that the pains continued, without the slightest relief from the treatment hitherto pursued, antimonial powder, in doses of six grains, was given; on the same evening the pain was less violent, and, by a continuance of its use, they became sensibly diminished in intensity each day, and, by the end of March, he was quite recovered.

Prolapse of the Uterus, caused by Labour.

This is the case of a woman, in whom labour took place very rapidly, and was followed by prolapse of the uterus, and violent hæmorrhage. Efforts were made by Dr. Sole to return it to its situation but without success, and consequently the woman was in a state of great danger, not only from the progress of the hæmorrhage, but also from the intense inflammation, which was caused in the uterus by its strangulation between the labia; snow and styptica were applied without success, and, after failing in his efforts at reduction, he was obliged to make several incisions with a bistoury, for the purpose of enlarging the opening of the vagina, after which the reduction was made with the greatest facility; a plug was then introduced into the vagina, and retained in that position by appropriate bandages; no ill consequence ensued, and in a few days she was convalescent.

HÔPITAL DE TRERIGLIO.

Removal of a Tumour, weighing twenty-four pounds, from the Neck.

Dr. Sacchi, Chief Surgeon to the Hospital, has lately removed from the neck of a girl, æt. 18, a tumour, 30 inches in circumference, and weighing 24 pounds; it extended from the parietal bone to the shoulders, and adhered to the spinous processes of the vertebræ; the interior was of an osseous structure, and was enclosed by a hard substance, resembling scirrhus. The patient went on favourably after the operation, and was discharged cured in four months.

Belladonna in Obstruction from Biliary Calculi.

A boy, ætat. 15, after exposure to wet and severe cold, was seized on the 30th of March with incessant vomitings, rigors, weight at the epigastrium, and delirium; these symptoms, which were unattended by fever, lasted three hours. For two days they returned at the same period, but the third attack was half an hour later, and more alarming in violence; opium and quinine were prescribed by Dr. Solatte, but, although they afforded temporary relief, still they did not prevent the daily occurrence of the paroxysm; ten days after the first seizure he was attacked in the night by an acute pain in the right hypochondrium, and tension of the abdomen; three days after this time the skin and conjunctiva became of a bright yellow colour, and the bowels were much constipated. In the space of forty days, all the remedies, which experience has recommended in such cases, were tried, but without any relief: suspecting the existence of a stone in the biliary duct, Dr. Solatte, whose patient the boy was, applied the extract of belladonna over the epigastric region and right hypochondrium; and, as the pains were diminished in violence by the application, he gave, internally, a pill, composed of the third part of a grain of the extract every two hours. On the 5th day, the dose then being half a grain every two hours, the patient became drowsy, when the hepatic pains entirely disappeared; within the course of the next three days he passed eight calculi, after which he recovered his usual health.

British Hospital Reports.

ST. THOMAS'S HOSPITAL.

Induratio Pulmonis.

CHRISTOPHER ANDERSON, æt. 33, sailor, a native of Sweden; admitted into William's Ward under the care of Dr. Elliotson, Sept. 12th, 1833; states that he had an attack of influenza four months ago; to which succeeded great difficulty of breathing, cough, and profuse expectoration, pain being almost entirely absent. Has now slight pain in the lower part of the right side: great difficulty of breathing, much increased by lying on the side affected; there is almost complete absence of the respiratory sound over the right side of the chest, except beneath the clavicle, where mucous rattle is heard; pulse quick and small. Was visited by Dr. Burton, in the absence of Dr. Elliotson, who ordered

Hydrarg. submur. gr. j.,
Extr. conii, gr. v., ter die.
Empl. lyttæ lateri dextro.

15th. Pain somewhat relieved, but cough is more frequent, especially during the night.

20th. Profuse expectoration has come on since yesterday; difficulty of breathing still continues, and is much increased when lying on the affected side.

23rd. Rep. empl. lyttæ lateri dextro.

27th. The pills to be taken now twice a day.

29th. The mouth has become slightly affected, which has been followed by some relief; respiration apparently bronchial; is now heard over a more extended space.

Oct. 4th Visited by Dr. Elliotson, who prescribed,

Ung. iodinæ (iodinæ 3i., adipis 3i., ft. ung.) lateri affect. infricand. per horam dimid. quotidie.

Tinct. iodinæ, ℥ v.;

Potass. hydriod. gr. ij.—Ex. aq. puræ, 3iss, bis in die.

6th. Feels greatly relieved; can now lie with more ease on the affected side; cough also is diminished, but the expectoration is still profuse, the matter expectorated being more fluid than hitherto.

8th. Tinct. iodinæ, ℥ x.;

Potass. hydriod., gr. v., bis die.

11th. More cough and pain in the chest; pulse rather sharp. Ordered V.S. ad 3x.

15th. The pulse was rendered softer for a time, but has regained its hardness; submucous rattle nearly all over the chest; respiration distinct at side. Ordered V.S. ad 3x., opii, gr. j., pil. hydrarg. gr. x., bis die.—Omit. mist.

18th. Blood bled and cupped. Pil. ter die sumendæ.

26th. Mouth affected; less difficulty of breathing; rattle much less distinct over the chest. Ordered, omitt. pil. hydrarg., cont. opium bis die.

29th. Cough is troublesome; pulse 84; considerable expectoration. Ordered opii, gr. j., ter die, sqr. smilacis asper. 3ss, 6tis.

Nov. 15th. Respiratory murmur heard over the whole extent of chest. Ordered portæ, half a pint daily.

Dec. 3rd. Has been improving rapidly; he still remains under treatment.

William Johnson, æt. 38, baker, admitted October 3rd, 1833, under the care of Dr. Elliotson. States that he has been ill a month. His illness commenced with pain in the chest, cough, and profuse expectoration, which still continue; respiratory sound is almost entirely absent on the right side of the chest, where the pain is principally felt; there is also dull sound on percussion, except beneath the clavicle, where it is more hollow than elsewhere; puerile respiration is heard on the unaffected side; pulse small and quick; tongue furred.

4th. Visited by Dr. Elliotson, who ordered

R. Ung. iodinæ mitius (iodinæ 3ss, adipis 3j. ft. unguent.), lateri dextro quotidie per horam dimidiam.

Tinct. iodinæ, ℥ v.,

Potass. hydriod. gr. ij.—Ex. aq. bis die.

8th. Tinct. iodinæ increased to ℥ x., and potass. hydriod. gr. v.

11th. Respiration heard at the side of the spine, and in the front and side of the chest; less dyspnœa and expectoration.

15th. Respiration heard further down the chest; much less dyspnœa and expectoration.

18th. Can lie on the right side; respiration heard over a greater extent of chest.

Nov. 5th. The respiration is not heard below the fifth rib on the right side in front, but is audible below the same level behind.

11th. Discharged; directed to continue the ointment and medicine some time longer.

WESTMINSTER HOSPITAL.

Extraordinary Phenomena.

A MIDDLE aged man, of very athletic and robust form of body, presented himself at the hospital a few days ago, in order to show himself to the surgeons and students of the establishment. He is completely covered with a green horny substance, in the form of quills, not dissimilar to those which are produced on the porcupine. The parts, which have escaped the deformity, are his face, the palms of his hands, and soles of his feet, every other part of his person is abundantly supplied with this green horny substance. He sheds his horns annually, and a fresh crop succeeds. He has been thus afflicted since his earliest infancy, and all the male members of his family, down from the great grandfather, have been similarly well furnished. His general health is excellent, and his secretions very regular.

A model has been taken of him in one of the Borough Hospitals.

Case of Burn.

A young child was admitted a few days ago, very severely burnt about the face and arms, and presenting a most piteous appearance. The extent of the injury was very considerable, and there was a good deal of fever. The child seemed to suffer much pain, and its breathing was slightly affected. The burnt parts were dressed, and stimulating remedies administered. Large quantities of brandy were given, and flour plentifully sprinkled over the surface of the injured parts. This treatment has proved very successful in some cases of burns which have been recently admitted into the hospital.

BOOKS.

AN Investigation into the Remarkable Medicinal Effects resulting from the External Application of Veratria. By ALEXANDER TURNBULL, M.D. 8vo. pp. . London: 1834. Longman and Co.

CORRESPONDENTS.

Dr. A. Thomson's communications have been received.

The Lecture of M. Roux has been received.

Mr. Swift.—Communications should be forwarded within the next ten days.

A Medical Student.—The rumour about a 100l. stamp, and 50l. for the diploma of the Royal College of Surgeons, is a hoax.

Medicus of Dublin.—The paper is too enthusiastic. We shall be happy to receive reports of cases.

A. Z.—The dose of strychnine is one twelfth of a grain, twice a day, in all the nervous disorders enumerated. After a few days it may be given three or four times a day.

Bibliophiles.—The arrangement of weekly journals precludes long reviews. Notices of books can only be expected, unless a production of great value is criticised.

A Reformer.—There will be an obstetric board at the Royal College of Surgeons.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXV., DELIVERED MARCH 26, 1833.

GENTLEMEN,—One circumstance, proving the connexion of cancer with constitutional causes, is the greater frequency of the disease in women, who bear no children, than in others who have families. This is a fact universally known and admitted; yet a female may have children, and even many, without being safe from an attack of the disease. One woman, I think, is mentioned by Sir Astley Cooper as falling a victim to cancer, though she had been pregnant not less than seventeen times. I have attended several women, who died of cancerous uteri, notwithstanding they were mothers.

Then, gentlemen, with reference to the prognosis and treatment of scirrhus and cancer, I may observe, what no doubt you are already well apprised of, that they are amongst the most intractable and fatal forms of organic disease to which the human body is liable. When you consider scirrhus as a new formation, as an adventitious growth or deposit, accompanied by the peculiar texture, which I have endeavoured to describe, you must naturally be led to suspect, that it is not a case over which medical surgery can have much power. Indeed, it is the belief of the most experienced and careful observers, that cancer, whether in the form of scirrhus, or carcinomatous ulceration, is absolutely incurable by any means except those plans, which bring about the total removal or absolute destruction of the parts affected. And even when this is done, a recurrence of the disease, either in the neighbouring tissues, or in remote parts and organs, will follow in a considerable proportion of the cases thus treated; another fact, confirming the truth of the doctrine, that cancer is a dis-

ease dependent on constitutional causes. When a cancerous disease is so situated as to admit of being entirely removed by means of the knife, no time, I think, should be lost in attempting to disperse the induration, or cure the ulcer, by other means. It is only while doubts prevail about the true character of the complaint, or while it is in a very early stage, that it is generally advisable to try plans which have in view the dispersion of the hardness, or the healing of the sore by external or internal remedies. The ground, on which I presume to offer you this advice, is, that all the medicines and applications, described in every pharmacopœia in the world, have already been tried for the relief and cure of cancer in thousands of instances, without the slightest advantage; and in innumerable cases, the time employed in the trial of them has afforded an opportunity for the disease to extend from the part originally attacked, and which might easily have been taken away at first, to other parts not admitting of removal, and the patients have died, without having had that chance of being saved, which a timely operation would have given them.

You will occasionally hear and read of cancerous affections being cured by various medicines and applications. But the question is, whether they were diseases really attended with the true scirrhous formation and structure, or genuine carcinomatous ulceration? Numerous swellings, indurations, and ulcers, have more or less resemblance in their outward characters to scirrhus and cancer; and such are sometimes dispersed, or healed; but that a disease, accompanied by the genuine scirrhous texture, the heterologous substance that distinguishes it, can be cured by medicine, or any local means, not acting so as to destroy the part affected like caustic, is a proposition, against which the voice of experience is loudly raised.

Believing in this fact myself, I shall be brief in the enumeration of a few of the principal medicines, which have been repeatedly praised for their efficacy in scirrhous and cancerous cases; for, according to the view, which I have taken of the subject, they have been ex-

toll'd without good foundation, and, in the trial of them, other diseases have been generally mistaken for those now engaging our attention. First let me mention *conium maculatum*, or *hemlock*, at one time praised up to the skies as a remedy both for cancer and scrofula. Then the extract of *belladonna*, a medicine which can only be given in very small doses, the effect of which is not to cure or stop scirrhus, or cancer, but to diminish the pain of the complaint. This is the most that can be said in favour of *belladonna*. Next I may notice *arsenic*, Fowler's solution of it, or the liquor arsenicalis of the London Pharmacopœia. I have frequently given it the fairest trial in cases of scirrhus and cancer; and am sure, that it has no power over them, though certain troublesome and inveterate ulcerations and tubercular diseases about the nose, lips, and other parts of the face, and on the tongue, will sometimes yield to it. Certain malignant looking sores on the face, reputed to be of a cancerous nature, were cured, under Mr. Carmichael, by exhibiting the *carbonate* or *phosphate of iron*, with the occasional use of purgative medicines. The dose of these preparations of iron varies from ℥j. to 3j. twice a day. They are now generally acknowledged to possess no specific virtues against true scirrhus and cancer. As for *mercury*, though it has the power of promoting the absorption of various indurations, and of curing different forms of the most obstinate ulceration, no modern surgeon has any confidence in its usefulness as a medicine for cancer. When the digestive organs are disordered in a patient with a scirrhus affection, when the hepatic functions are deranged, sometimes small doses of the blue pill, or compound calomel pill, with leeches on the epigastrium, or hypochondrium, and aperient medicines occasionally, will improve the general health, and put the patient into a better state for an operation; but neither this, nor any other medical plan, will serve to disperse a true scirrhus. The *muriate of barytes* has been tried, but it is now given up, as entitled to no confidence. Living altogether on a *milk*, or *vegetable* diet, or a diet just sufficient to keep the body and soul together, something very nearly approaching to starvation, is one of the schemes which have been resorted to. In the periodical works of the day, you will read of cancerous diseases yielding to *iodine*. At the Bloomsbury Dispensary, we have frequently tried it for such complaints in the breast, uterus, and lips, but without success.

Amongst the favourite *topical applications*, is the *liquor arsenicalis* properly diluted. *Arsenical pastes* are dangerous applications. I remember a patient being poisoned with them; he had a cancerous ulcer of the face; the surgeon covered it with the paste; and he died in a few hours from the absorption of the arsenic, and its deleterious effects on the system. If you are bold enough to attack cancerous diseases with caustic (which I am not) abstain at all events from arsenic, and employ

pure potash, though, I think, you will often kill the patient even with this.

Narcotics, in the form of plasters, are sometimes employed, particularly *opium*, *conium*, *hyoscyamus*, and *belladonna*, blended in various proportions with the ordinary brown soap plaster. The *watery solution of opium*, and the *liquor opii sedativus*, you know, are common applications for all kinds of malignant ulcerations. In addition to these articles, I will merely refer to *carrot poultices*, *fermenting poultices*, a solution of ʒj. of the *sulphate of iron* in lbj. of *distilled water*; a paste composed of *carbonate of iron* blended with water, or sprinkling the ulcer with the powder; the solutions of the chloride of *lime* and *soda*; and covering the scirrhus part with a piece of hareskin, or fleecy hosiery, so as to protect the disease from the influence of vicissitudes of temperature, and the injurious effects of accidental blows.

Now, gentlemen, as none of these plans and medicines will cure cancer, you are obliged to consider what benefit may be obtained by extirpating the diseased part.

If the operation be done early, and performed on the principle of removing, not merely what is obviously diseased, but a good deal of the substance around the scirrhus or cancer, the result will frequently be a permanent cure, as far as that part is concerned. But the cure is not a certain thing. Indeed, after a cancerous tumour has been extirpated, whether the disease be indolent, or painful, small, or recent, there is no certainty that the disease will not return. On the other hand, it is not certain that the disease will return, even when it has made considerable progress previously to the operation. But, it is an undoubted fact, that the more recent the disease is, the less are the chances of relapse.

Hence, as you have no medicine which will cure scirrhus and cancer, you should recommend an operation for their removal as soon as no doubt exists about their nature. The prospects of the permanent success of the operation will also be greater, if, after its performance, you do not immediately think that every thing has been done that ought to be done. On the contrary, men of great experience find, that keeping the patient for some time afterwards on an alterative plan of treatment will materially lessen the risk of a relapse.

When it is impracticable to remove the whole of the diseased parts, it is a rule in surgery not to undertake an operation at all. The partial extirpation of a true scirrhus, whether by caustic or the knife, is sure to convert the disease into a fatal painful carcinomatous ulcer.

Another maxim in surgery is, never to perform the operation for the removal of a cancerous tumour when there is reason to believe, that the disease is not confined to the part, but has already extended itself to glands and several other textures more or less remote from the original seat of the disease.

What good can arise from cutting away a cancerous breast, when, perhaps, all the absorbent glands about the axillæ, neck, and within the sternum, are similarly affected? Where can be the prudence of cutting away an external scirrhous when there are cancerous depositions in the lungs, liver, bones, or other deep-seated textures?

Surgeons do not decline to operate when the axillary glands are diseased together with the breast; and when the whole disease in each situation can be thus removed, I consider the practice right; but, certainly, the extension of the disease to those glands very materially lessens the chance of a permanent cure. It shows, that the diseased action has passed to organs more or less remote from the original affection, and that the system may be inveterately under its influence. The celebrated Camper believed, that a sure sign of the incurability of a cancerous breast consisted in a shooting pain between the second and third ribs. He was convinced, that such pain denoted the extension of the disease to the lymphatic glands under the sternum. Gentlemen, let me advise you always to prefer the knife to caustic for the extirpation of cancerous diseases.

Is it right to operate when the disease is in the ulcerated state? The answer must depend upon circumstances. If the whole of the diseased parts can be removed, if the viscera of the chest and abdomen appear not to have suffered, and the lymphatic glands are not extensively affected, the operation is justifiable, though its chances of success are much less than those where the case is only a scirrhous, under similar conditions. The lips, however, have been removed in the ulcerative stage, without the disease afterwards extending itself to the submaxillary glands, or any relapse taking place. The same fact has been exemplified after the extirpation of portions of cancerous tongue.

When the opportunity for operating has passed away, palliative treatment is all that can be attempted. Appeasing the pain by the application of the watery solution of opium, or dressing the ulcer with the liquor opii sedativus, or with an ointment containing ℥j. of the powder of opium in every ounce of lard, are very rational methods. I had one patient lately with a dreadful carcinomatous ulceration of the breast. She found no dressing afford her so much ease as the common spermaceti ointment. The foetor may be lessened by applying the chloride solutions; but they give not the ease derived from other dressings. To a scirrhous which it is not judged advisable to remove, you may apply soap plaster, containing a proportion of the extract of belladonna or hyoscyamus; or you may simply cover the part with a piece of soap plaster or soft fur. On account of the pain, the acetate or muriate of morphia may also be prescribed. This practice is most particularly called for in ex-

amples of ulcerated cancer. Where the agony is great, the disease is generally incapable of removal by the knife; and all that can be done is to render the patient's journey to the grave more free from misery.

The success of an operation will materially depend upon the whole disease in the part—every atom of it—being completely extirpated. I recommend you, in particular, always to make a free removal of the skin and cellular membrane around a scirrhous tumour, as the ligamentous bands frequently extend to a considerable distance around the perceptible induration and swelling. In a certain number of instances, a relapse will unfortunately take place, whatever be the precautions taken in the performance of the operation. The chances of recovery, however, are much greater after an early operation, when the disease has made but little progress. The prospects of a radical and permanent cure are also more promising when the operation has been properly performed, and strict attention is afterwards paid to the patient's general health. Hence, when you take away a scirrhous, do not think that you have fulfilled the whole of your duty to your patient; but give him such medicines, and keep him on such a regimen, as may be likely to produce a beneficially alterative effect on the constitution.

When the disease extends only to one or two of the axillary glands, and the patient seems to be free from organic disease in the chest and abdomen, you may perform the operation; but you will have to remove the diseased gland or glands in the axilla with the knife, after you have extirpated the scirrhous of the breast. The chances of recovery in such a case, however, are not equal to those in which the breast alone is affected.

The next specific disease, gentlemen, which I mean to describe to you is *fungus hematodes*. This was so named by Mr. Hey, in consequence of its tendency to throw out, with great rapidity, a large bleeding fungus-like substance, after ulceration of the skin has taken place. It is sometimes called *soft cancer*; and, by Mr. Abernethy, was named *medullary sarcoma*, from the resemblance it bears to the medullary substance of the brain. It is, in fact, very similar to the substance of the brain in all chemical and physical properties. Commonly it presents itself in masses, contained in fine membranous partitions. It is generally of the same consistence as the cerebral medulla; but, sometimes, it is much softer. It varies also in colour: in some instances it is quite white; in others light red; and it has occasionally been found to be of a deep red colour. A section of the tumour exhibits numerous bloody points. When superficial, it begins as a colourless swelling, soft and elastic to the touch, unless bound down by a fascia, in which case it has a firm tense feel. When immediately subcutaneous, it is elastic, and hence liable to be mistaken

for a tumour containing fluid. When it occurs in the testicle, it is frequently supposed at first to be hydrocele.

Like cancer, it has a tendency to spread to the absorbent glands, which become converted into a similar substance. In every sense of the expression, it is a new formation, an adventitious growth, whether situated in the cellular membrane, in the tissue of the muscles, in that of the viscera, or within the orbit, or in any cavity or on any surface of the body. When it occurs in deep seated parts, it has an invariable tendency to make its way to the surface, and when this happens, a considerable swelling arises, the skin at length becomes thin and discoloured, and from being at first smooth, now projects irregularly; openings are formed in these projections, and a medullary growth springs up, which sometimes bleeds profusely. It is only at this period of the disease that the name of fungus hæmatodes is at all applicable; and even now it is not very correct, as the mass is not a fungus, but usually a substance of medullary consistence. As far as I have observed, medullary sarcoma is a constitutional disease, and rarely confined to one organ. It has been observed in the lungs, the heart, the liver, the spleen, the kidneys, the uterus, the ovaries, the mammae, the mesenteric glands, the dura mater, and the thyroid gland, of which there is a fine specimen in Mr. Langstaff's museum. We have before us many specimens illustrating this disease in various parts of the body. Here is an instance of fungus hæmatodes of the kidney, taken from a child only two years old. Here is a preparation, in which the disease is seen enveloping the head of the tibia; it was likewise taken from a child, and I may now remind you again, that this disease is frequently seen in children. The next preparation shows the extension of the disease from the antrum to the brain, through the orbital plate of the ethmoid bone. Fungus hæmatodes appears, then, to be a disease of the whole system, and hence the generality of operations, undertaken for its extirpation, have not had the desired effect.

An early symptom of this terrible and very common organic disease, is a wan, pale complexion, such as is remarkably indicative of what may be termed a fatal organic disease. The patient generally dies hectic. One of its differences from cancer is, that it contains within its substance no ligamentous bands, or central hard nucleus, but consists of a soft pulpy matter contained within septa, composed of a fine delicate membrane. In order to be able to see its structure well, you should subject it to maceration or the action of alkalies. Now a scirrhus tumour is generally firm, hard, and incompressible from the very first; whereas there is a softness and elasticity about fungus hæmatodes, at once constituting quite a different character. The parts in this latter disease are not destroyed by ulcera-

tion, as in cancer. Fungus hæmatodes frequently attacks the liver, the spleen, the kidneys, and lungs, *primarily*; whereas it is alleged by some pathologists, that cancer only attacks these organs *secondarily*; a point, however, deserving of further investigation. Fungus hæmatodes is a disease of young subjects, and persons below the middle age, whereas cancer chiefly attacks individuals between the ages of forty-five and fifty, or older persons. With regard to the treatment of fungus hæmatodes, we know of no medicine which can correct the state of the constitution upon which this disease depends. The only chance we have of curing it is by the removal of the tumour at an early period of its formation, before the lymphatic glands and several other parts of the body have become affected. Thus, if the disease has extended up the spermatic cord, castration will be of no avail. I am of opinion that the viscera generally become diseased much sooner in cases of fungus hæmatodes externally situated, than is generally supposed. I am now speaking of that form of fungus hæmatodes, which comes under the care of surgeons, where the surface of the body, or the limbs are the seats of the disease. The fact, which I have just now mentioned, partly accounts for the general failure of operations. Fungus hæmatodes, as I should have explained, sometimes attacks the bones, commencing in the medullary, or cancellous texture, destroying their walls, and then making its way, by the annihilation of other tissues, to the surface.

Notwithstanding there is every reason for believing fungus hæmatodes to be a constitutional disease, and we find that, after an operation, there is usually even a greater disposition to relapse, than is manifested in examples of scirrhus and cancer, experience occasionally brings forward cases forming exceptions to this statement. I removed a testicle affected with fungus hæmatodes from a man more than two years ago; yet he remains perfectly well; and you will sometimes hear of the same disease in the eyes, breast, and limbs, being effectually extirpated by operation, without being followed by any return of the complaint. Unfortunately, the contrary more generally happens, so that the prognosis, which you deliver, should be qualified by a reference to this important fact.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE VII.

Organic Disease of the Stomach—Diseases of the Digestive Tube.

GENTLEMEN,—In speaking of the employment of counter-irritation in cases of chronic

gastritis, I forgot to mention the use of friction with croton oil, which has been found beneficial in many cases of chronic inflammation. It has been extensively used by many practitioners in the treatment of chronic affections of the joints, and in various forms of pulmonary disease; and I have employed it myself in some cases of chronic gastritis with benefit. I cannot say that the cases in which I have used it presented all the symptoms of chronic gastritis, but they were certainly cases of chronic gastrodynia, with severe local pain, nausea, and loss of appetite. It is an excellent counter-irritant, and gives very little pain. The mode in which I employ it is this,—take a few drops of croton oil, five or six, for instance, drop them on the epigastrium, and rub them in with a piece of lint or bladder, interposed between your finger and the skin, and the next day you have an eruption of small papulæ, which you can increase at will. There is one interesting circumstance connected with the use of croton oil frictions, which you should be made acquainted with. The liability to produce counter-irritation, seems to depend upon the absorption or non-absorption of the croton oil; if it be absorbed it will purge, but if it be not it will produce counter-irritation. In cases of this kind, therefore, where it produces the necessary degree of irritation in the skin, the chances are, that it will not act disagreeably by bringing on catharsis. I have only seen one case where there were both the eruption and catharsis. This was a gentleman who had lately suffered from dysentery in warm climates.

I may also mention, that, in convalescence from an attack of chronic gastritis, you must pay great attention to diet for a long time, because there is no affection of any organ in the body, in which an error in diet so rapidly induces a return of the original symptoms, as in disease of the stomach, while each return of the disease renders the attack more dangerous and unmanageable, until at last disorganisation takes place.

This leads me to speak of organic disease of the stomach. On this subject I shall be very brief; the best mode of communicating information will be to exhibit these preparations; you will derive more instruction from their inspection than from any lecture I could deliver. (Dr. Stokes here exhibited a number of beautiful preparations, from the Park-street museum, illustrative of various organic lesions of the stomach.) Here is a case, which some pathologists would call cancer, others chronic gastritis. I may remark here, that pathologists are divided as to what is the cause of cancer of the stomach, but the best informed are of opinion that, in those cases of gastric disorganisation, which are called cancer or scirrhus, all that can be demonstrated by the knife is referable to the results of chronic inflammation. This is a different proposition from saying, that chronic inflammation *alone*

will produce cancer. As yet we know little of cancer; dissection of cancerous organs gives but scanty information; but this seems certain, that, in particular conditions of the economy, an inflammation of the stomach will end in cancerous disease. Here is an excellent preparation of the stomach of a person who died of cancer of that organ. For several years before his death he had a jaundiced look, an emaciated appearance, frequent vomiting, and severe pain towards the termination of the digestive process, a circumstance which denotes disease of the pylorus. He also had hæmatæmesis. You see the inner surface in the vicinity of the pylorus presents ulcerations of the mucous membrane and thickening of the sub-mucous cellular tissue. The pylorus itself does not appear to be at all contracted, but the parts around it are in a state of extraordinary disease. Look at the preparation again, and say what could bitters, or acids, or alkalies, or tonics have effected in a case of such extensive disease. Here is a stomach, in a state of long continued chronic inflammation, and exhibiting lesions, which some would designate as cancer of that organ. Now, though I do not know the treatment which this patient underwent, I would venture to say, that he took plenty of the usual anti-dyspeptic medicines. Yet in a vast number of cases, where enormous quantities of these remedies are taken daily, the stomach is in as bad a state as that preparation exhibits, and I feel the more strongly convinced of this, because I am aware that many persons die after having gone through the whole routine of anti-dyspeptic practice, and, when they are opened after death, incurable disease of the stomach is discovered. Here is an example of vast cancerous disease of the stomach; here is a very interesting specimen of chronic gastritis, chiefly representing a most remarkable and circumscribed ulcer at the termination of the stomach. Here you see is the ulcer, with raised, thickened, and introverted edges. Now, in all probability this ulceration was exceedingly chronic, for you perceive nature has been at work with it, and has made some attempts at reparation. It is in such a case as this that patients generally refer their pain to a particular part of the stomach: digestion goes on without any pain until the food reaches a certain point, when acute pain is felt, and this continues until it is relieved by vomiting. The occurrence of this symptom, after an attack of acute gastritis, would lead you to suspect the formation of one or more ulcers, and the persistence of this localised pain should induce you to persevere in employing every means in your power calculated to remove the disease. The preparation which I now exhibit is interesting, as it shows the effect of corrosive poison on the stomach. The patient, to whom this stomach belonged, died in consequence of swallowing a quantity of sulphuric acid; here you see the consequences, the mucous

membrane is black and disorganised, exhibiting this ragged appearance. In some cases of malignant fever we have found the stomach presenting somewhat similar appearances; and the same state of the stomach is described by some writers as occurring in cases of intertropical fever. Here is a preparation, which you should inspect, chronic gastritis with a large ulcerated patch in the centre of the stomach. Here is another example of extensive cancerous disease.

A very few words will suffice for the state of the science on the subject of cancer of the stomach. It is very hard, nay, even almost impossible, to draw a line of distinction between the symptoms of cancer of the stomach and chronic gastritis, and I believe it is admitted on all hands that the same causes give rise to both. Long continued irritation will, in one case, produce cancer of the stomach, in another, chronic gastritis. Again, it is admitted by many, that what is called cancerous ulceration of the stomach has no appreciable difference from ulceration in various other organs; and hence some persons have gone so far as to say that there is no such thing as cancer of the stomach (separately considered); and that all the cases adduced of it are nothing more than so many forms of chronic gastritis. In the present state of medicine, we are not, indeed, possessed of any data which would enable us to come to a final determination on this question. It is certainly impossible to determine this point; but if there be anything peculiar in cancerous matter, similar to tubercular or melanotic matter, there is no reason why, under the influence of inflammation, it should not be developed in the stomach, as well as in any other part of the body. But whatever views we entertain on this subject, we must confess that, in the majority of cases, there is a chronic gastritis, and that the principles of treatment which would alleviate the patient's sufferings and prolong life, *are those which are calculated to prevent the occurrence of gastric inflammation.* The more you approximate the treatment of cancer to that of chronic gastritis, the greater comfort will you afford your patient, and the more will you prolong his existence.

The most celebrated case on record of this affection is that of the Emperor Napoleon. He died with extensive ulceration of the stomach, which, of course, was called "*cancerous*," and there were also distinct traces of disease in the liver, the mucous coat of the intestines, and the lungs. His disease was believed by himself to have originated in the stomach, and to this opinion he adhered, notwithstanding the results of some solemn consultations, at one of which his affection was declared to be an "*obstruction of the liver*," with a "*scorbutic dyscrasy*." At another it was pronounced to be a "*chronic hepatitis*," and a course of mercury recommended! When we reflect on this, and read in the account by Gaubert (which you will see in the *Examen*

des Destinies Medicales), the regimen which was used, and the list of stimulating medicines employed, you will not wonder at the words of this great man, when he was pressed to take more drugs, to swallow the universal nostrum, mercury, to which he had the greatest aversion. "Your disgusting preparations are good for nothing. Medicine is a collection of blind prescriptions, which destroy the poor, sometimes succeed with the rich, but whose whole results are more injurious than useful to humanity." But he got mercury, notwithstanding, mercury for his "digestive organs;" to "excite the liver;" to "remove its obstruction," and mercury to create bile, and purgatives to remove it; and tonics, and antacids, and stimulants; and he died in torture, and his body was opened, and the stomach was found "*cancerous*."

I should not omit mentioning to you, that in those cases of chronic gastritis, which run on to an incurable stage, the best treatment consists in a careful regulation of diet, in keeping the bowels open by enemata, or the very mildest laxatives, and in avoiding every thing capable of producing excitement. You will also derive advantage from the employment of gentle counter-irritation, and from the internal use of narcotics, which in such cases appear to have a more beneficial effect than any other class of remedies. With the exception of these, I do not know any other kind of medicine you can safely employ? and I believe that, in the majority of cases, you will find that the patients have taken already a great deal too much medicine. Anxious for relief, and urged on by the hope of obtaining some remedy capable of alleviating their sufferings, they have recourse to every grade of quacks, are persuaded to swallow every kind of drug, and are subjected to every form of harassing and mischievous treatment. The diet which you prescribe for such patients should be sparing but nutritive; give the stomach as little to do as will be consistent with the support of life and strength; and you may take it as a general rule in the treatment of all chronic affections of the digestive tube, whether cancer of the stomach, scirrhus of the pylorus, or stricture of the intestines, that there are two great principles of general application, preserving a gently open state of the bowels, and allaying inflammatory excitement.

Let us now proceed to the remaining parts of the digestive tube, of which the next in order is the duodenum. I shall not dwell much to day on the subject of duodenitis, because I shall revert to its consideration when speaking of jaundice, because inflammation of the duodenum is a common cause of jaundice, perhaps the most common, if we take the whole of its cases together. You are not to suppose that I wish to inculcate the doctrine that jaundice is a necessary complication in duodenitis, but it has been proved, that there is an extraordinarily frequent coincidence between both,

and that jaundice very often seems independent of any mechanical cause, such as an obstruction of the biliary ducts. So far from this, that, in some cases, particularly those which are produced by, or accompany, a duodenitis, we have intense universal jaundice at the same time that the bile is flowing freely into the digestive tube.

The researches of the immortal Bichat gave the first hint which directed the attention of practitioners to the circumstance, that, in many cases where jaundice had existed during life, there was no obstruction or disease in the liver or biliary ducts, but that in such cases there was always more or less inflammation in that part of the digestive tube, into which the bile was immediately discharged, and this led ultimately to the discovery of the connexion which exists between inflammation of the duodenum and jaundice. In treating of the sympathies which depend upon continuity of surface, Bichat refers to the connexion which exists between the surfaces of mucous membranes and the ducts which open on them, and endeavours to show, that the natural mode of excitement in all secreting glands is a stimulus applied to the surface on which their ducts open. As examples of this, he instances the effect which food and other substances, applied to the mucous membrane of the mouth, have in stimulating the salivary glands; the effect which stimulants, applied to the conjunctiva or nose, have on the lachrymal gland, and many others. Hence Broussais concludes that, when the mucous surface of the duodenum is thrown into a state of excitement, we may have a consequent affection of the liver, for the duodenum bears the same relation to the liver as the mouth does to the parotid glands. That this is frequently the case, I think, is very probable. It is now established, that the cause of the yellowness in what has been called yellow fever, is disease of the upper part of the digestive tube, in which the duodenum is always involved; and that the fever itself (the typhus icterodes of the nosologists) has been found to be greatly connected with inflammation of the stomach and duodenum. During the epidemic of 1827, we had in the Meath Hospital a great many cases, which bore a striking resemblance to the yellow fever of warm countries, and particularly in this, that they were accompanied by intense jaundice, and inflammation of the upper part of the digestive tube. You will see in the works of Rush and Lawrence, two of the best American writers on yellow fever, that, of the numerous bodies they examined, there were scarcely any in which the jaundice was found in connexion with liver disease, but that in all cases there was intense inflammation of the digestive surface. I shall return to this subject when I come to speak of liver disease.

With respect to the jejunum, I may state that we know very little of the symptoms which characterise inflammation of this part

of the intestinal canal; and it is a curious pathological fact, that this portion of the tube is, of all others, the least liable to inflammation.

In point of fact, we have no means of ascertaining what are the prominent symptoms of inflammation of the jejunum, because, in almost every case in which jejunitis has been discovered, there has been also extensive disease of the rest of the small intestine. We have cases of simple gastritis; there have been also cases of distinct disease of the duodenum. We may have disease in the lower third of the ilium, unaccompanied by an affection of any other part of the tube. The same thing may occur in the case of the cæcum, colon, or rectum, but it seldom or never occurs so far as the jejunum is concerned. I shall therefore pass over jejunitis, and proceed to draw your attention to one of the most important diseases to which the human subject is liable—*inflammation of the ileum*.

Inflammation of the ileum is a most important affection, for two reasons; first, in consequence of its extraordinary frequency, and, in the next place, of its insidious latency, the disease generally requiring a considerable degree of tact and experience on the part of the practitioner to make out its diagnosis with certainty. In fever, it is the most frequent of all the forms of intestinal inflammation; and hence Broussais, finding inflammation of the ileum of such constant occurrence in fever, concluded that fever was only symptomatic of intestinal inflammation. Further researches have shown that he was mistaken, and that the inflammation of the digestive tube is, in many cases, secondary; but it is still a circumstance of almost constant occurrence, and in many cases of fever is the cause of death. Now, the portions of the intestinal tube most commonly affected in fever are, the stomach and lower part of the ileum, and the frequent occurrence of this in fever is very remarkable. There are few cases of typhus without it. In some cases of typhus you will, on examination after death, be astonished to find extensive disease of the intestinal canal, which, during life, had not attracted any particular notice, and this you will most commonly find in the lower part of the ileum. So common is it, that Louis says that ileitis is the grand anatomical feature of typhus fever; that is, had he been obliged to pitch on the lesion of some particular organ as giving a character to typhus, he would say that it was ileitis. There are other diseases, too, in which inflammation of the ileum forms the principal complication. In the diseases of children, which go by the names of worm fever, remittent fever, and bilious fever, I believe that ileitis is generally the first affection, and that the fevers are only symptomatic of it. It constantly occurs at some period or other of tabes mesenterica; and I believe, that in many cases it precedes the affection of the mesenteric

glands. It is exceedingly common in phthisis. In every case of phthisis, where diarrhoea has lasted for some time, the probability is, that there is ulceration in the cæcum, colon, and lower part of the ileum.

Now, what is the nature of this ileitis? This preparation (*handing one for inspection*), which I beg of you to hand round, will furnish a very good illustration of the disease. Here is a portion of the intestine exhibiting various distinct ulcerations of different sizes, occupying the situation of the mucous glands. I do not mean to say, that the character of the disease consists in this distinct ulceration; it is an essential disease of the mucous membrane, and of its glands, which exist in great numbers on the surface of the lower third of the ileum, and are called *solitary* and *aggregate*. These glands frequently take on the inflammatory condition, become softened, run into ulceration, and produce extraordinary sympathetic irritation of the whole system. There has been lately a great deal of discussion with respect to the question—Whether disease begins in the glands or in the mucous membrane, and whether we can separate disease of the glands from disease of the mucous membrane. This has been carried to a great extent; and a change has been attempted to be made in the name of the disease, it being entitled *dolhin-enteritis* by those who say that the inflammation commences in the glands. But this I think is a mere refinement, and is carrying the thing too far. It is next to impossible for the glands to be affected without involving the mucous membrane, or for the mucous membrane to be affected without an extension of the disease to the glands. We sometimes, however, see the mucous membrane diseased without the glands being apparently engaged; but I think the glands are never engaged without the co-existence of disease in the mucous membrane. In this preparation you see the mucous membrane is just giving way; and here is an actual slough, where the mucous and submucous tunics have yielded to the inflammation. In the lower portion of the ileum we meet with an infinite variety in the size and number of the ulcerations: in some they are very close and numerous, in others there are only two or three detached ones; in some, the whole circle of the intestine is destroyed, and the ulcer is nearly as broad as the palm of your hand. It is interesting to consider, with respect to the pathology of the respiratory and digestive systems, how it comes, that ulceration of the mucous membrane is so much more common in the digestive apparatus than in the respiratory. For one ulceration of the bronchial mucous membrane from acute disease, you will have one hundred of the gastro-intestinal. For this peculiarity we cannot clearly account; but there seems to be more development in the digestive than in the respiratory system, and that this over-development produces a ten-

dency to disease. This, perhaps, is an approximation to an explanation of the facts; and to this may be added, that the mucous membrane of the intestines is exposed to the influence of a much greater variety of agents. It is difficult to give an accurate idea of the symptoms of ileitis, as we can only arrive at a knowledge of it by negative evidence, or, as the French term it, "*par voie d'exclusion*."

In a case of gastritis and of inflammation in the upper part of the digestive tube, the most prominent symptoms are thirst and vomiting. In this affection, too, there is thirst, but it is by no means so urgent as in the former cases, and there is generally no vomiting. In a case of acute gastritis there is always a desire for cold drinks. In this disease there is also a desire for fluids, but the patient prefers them warm. Here you perceive two symptoms, connected with the predominance of disease in the upper part of the digestive tube, are absent—vomiting and the desire for cold drinks.

Now, you are aware, that, in a case of inflammation of the colon and rectum, the most prominent symptoms are diarrhoea, tenesmus, and the passing of a quantity of morbid secretions. These symptoms, in a case of ileitis, are either wanting, or they are so slight as to excite but very little notice. If, then, in a case of intestinal disease, we abstract the characteristic symptoms of disease in the upper and lower part of the digestive tube from the phenomena of the existing disease; if we find that it presents symptoms which do not properly belong to either the stomach, duodenum, colon, or rectum; we conclude that it must depend on a lesion of the remaining part of the canal, and we are, in this way, led to the diagnosis of ileitis. Let us enumerate the symptoms of an ileitis. In the first place, thirst, without a preference for cold drinks; in the next, absence of vomiting; again, in the early period of the disease, there is generally a tympanitic state of the belly, and the patient seldom complains of pain even in fatal cases. This a point of extreme importance. There is, however, most commonly a degree of tenderness over the ileum, which you will be able to detect by an accurate examination, and this tenderness presents a remarkable difference from the tenderness of gastritis, both in degree and situation. It is very seldom so exquisite as in a case of gastritis, the patient can bear a considerable degree of pressure, and the tenderness, in place of being towards the epigastrium, is situated between the umbilicus and the crest of the ileum on the right side; here pressure excites pain. The tongue in this affection is generally of a dirty white, pointed, and red along the edges and tip; the pulse is quick and small, and the face is contracted. As to the nature of the discharges from the bowels they are exceedingly various; there has been as yet no diagnosis founded on their appear-

ants, and in some fatal cases they have been observed to retain an almost perfectly healthy appearance throughout. What would the gentlemen, who draw their diagnosis from chamber-pots, say in such cases? I have seen perfectly natural stools in cases, which immediately after have terminated fatally, and where, on examination after death, there was a vast extent of ulceration in the ileum. In addition to the symptoms just recited, the patient most commonly has fever, and this presents itself under various forms, frequently assuming the type of a simple continued fever; hence, in a great many cases, *the patient is merely supposed to labour under simple continued fever, and the existence of extensive inflammation of the ileum is entirely overlooked.* In other instances, there is more or less prostration, which increases with the progress of the disease, and the fever frequently receives the appellation of typhoid. Under these circumstances, the patient often gets bark and wine, every means is taken to support his strength and remove the typhoid condition of the system, the inflammation of the intestine is exasperated by neglect and mal-treatment, the patient dies, and, on dissection, the ileum presents an enormous sheet of ulcerations.

In cases of this kind, where the diagnosis depends as much on negative as on positive circumstances, it is of importance to have a direct sign, by which we may be able to ascertain with some degree of certainty the existence of a suspected enteric inflammation, and I think I have discovered one, which I believe has not been as yet noticed; this is increased pulsation of the abdominal vessels. In many cases of acute inflammation of the brain, the increased pulsation of the carotids has been frequently remarked, and every one sees that, under such circumstances, there is an undue excitement of these vessels, or, in other words, that there is a want of proportion between the action of the carotids and that of the arteries of the extremities. If your finger be attacked by paronychia the same phenomenon is observed, the artery leading to the inflamed finger beats much stronger than the artery of the corresponding one on the opposite side. From these circumstances I was led to conclude that, in cases of acute inflammation of the digestive tube, there would be increased pulsation of the abdominal aorta; and, on following up the investigation, by examining several persons who had distinct and well marked intestinal inflammation, I found that my conclusions were well grounded. In such cases, I found not only a remarkable throbbing of the abdominal aorta, but I also discovered that this throbbing was prolonged to the femoral arteries, and that, on the other hand, there was little or no corresponding excitement in the arteries of the upper extremities.

CLINICAL LECTURES

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, &c. &c.

At the Westminster Hospital.

LECTURE IX.

On the Anatomy and Diseases of the Bladder and Urethra.

GENTLEMEN,—There were two cases in this hospital some short time back, proving the observations I have made to you. In the first instance, a man was brought in very ill, indeed almost in a dying state with complete retention of urine and died. Mr. Taylor, your late house-surgeon, dissected the parts carefully. This person had but one stricture, which you see at three inches from the orifice of the urethra: it is narrow, but complete; and the canal is so much dilated behind it, that a golden pippin of a large size might have been readily placed in it. Nothing was done for this man by those he consulted before he came to the hospital, nevertheless, the simplest puncture by a lancet pushed into this dilated part would have saved his life, if it had been done in proper time. This is one of the best cases I have seen to show the way in which the urethra will dilate behind a stricture, and, at the same time, the corresponding thickening of the coats of the bladder. It is an admirable instance of bad surgery, and demonstrates the necessity that exists for some legislative interference, which shall cause persons, who call themselves surgeons, to be at least reasonably educated; so that, when a man takes upon himself the office of a surgeon, the poor and the ignorant, who may not know much about the matter, may place some reliance on the fact of his having some knowledge of the art, if not of the science, of his profession. I was sent for, about four years since, to Market Street, beyond St. Albans, to see a man nearly in a similar situation. The scrotum was greatly swollen, and was half as large as my head. The urethra, just where it begins to be covered by it, was dilated, so as to form a distinct protuberance, and the skin covering it was black. Nature was going to relieve herself, by making an exit for the urine, by destroying the parts posterior to the stricture by mortification. The ulcerative process necessary to complete the object had, however, allowed the urine to escape into the cellular membrane of the scrotum. The man seemed to be dying, and there was no time to lose. I therefore at once cut into the urethra, through the slough and through the stricture. The gush of urine which followed gave complete relief. I then made several incisions into the cellular tissue of the scrotum, and squeezed out as much as possible of the urine, introduced a catheter into the bladder through the whole length of

the urethra, and returned to London, not expecting to see him again. He called on me, however, some three months afterwards, in good health; the scrotum had not sloughed so much as might have been expected, for which he was indebted to the free incisions made into it. The urethra had contracted again, and the parts were in many respects deformed, but he felt quite satisfied, and grateful for his life preserved.

The other preparation is also from a person who died in this hospital of inflammation of the lungs. As he was known to suffer from great difficulty in making water, I had the diseased part of the urethra removed. The stricture is a narrow one, at five inches from the orifice, and would only admit the point of a large lachrymal probe to pass through it. This small opening was at the upper and outer part; the urethra behind was not, nor is not in the slightest degree dilated, although he had, for some years, laboured under the complaint. I am induced to believe, from these and other similar cases, that the anterior and posterior parts of the urethra dilate more readily than the middle portion.

A stricture of the urethra is, then, I believe, always a result of inflammation; for, although in some few individuals, the origin may be apparently doubtful, I am inclined to believe, that, if the patient's early history could be accurately investigated, or ascertained, the disease would always be found to have been preceded by inflammation. I have known stricture form in consequence of the passage of calculi from the bladder at an early period of life; but this is by no means a common cause, although the complaint is sufficiently frequent among children; and when strictures do form in such cases, they usually follow as cause and effect, the small stone in its passage having been arrested long enough to produce inflammation, and, in all probability, ulceration at some particular part. The urethra of a very young person or child is not prone to form a stricture: it does not do so without a greater degree of inflammation and ulceration than will give rise to it in an adult; and it seems again to obtain this immunity at an advanced period of life. It is probable, that the urethra, about the age of puberty, like every other part of the body, receives a development independently of size, which renders it more susceptible, and which it loses again at a later period of life. Be this as it may, stricture of the urethra is the disease of young men, and not of old ones. An old man may have stricture from his youth, but he never applies to you at sixty, or even fifty, years of age with such a complaint, without being aware that he has long laboured under some disease in these parts. If he states that his complaints have only come on of late, you may rely that the neck of his bladder is in an irritable state, or has lost its natural elasticity, or that his prostate is diseased, or, at all events, that the complaint is in the prostatic

part of the urethra, and not in that portion which is usually the seat of stricture in younger persons.

Disease of the kidney will often give rise to acute pain at the neck of the bladder, and even at the extremity of the penis. These parts may have become inflamed as well as irritable; the natural action of the urethra may be deranged in consequence, and irritation, inflammation, and stricture may be established in succession, in young persons, in its bulbous portion becoming membranous. An injury on the perineum may readily, and with due relation to cause and effect, give rise to it; and long-continued irritation from disease of the rectum will do the same. Serious wounds of the rectum do almost always give rise to retention of urine, requiring the passage of the catheter, which becomes an important part of the treatment during the first days of inflammatory action; and where neither the bladder nor the urethra have been injured, the difficulty is usually found to exist at the membranous part of the urethra, and not at the neck of the bladder, and is dependent upon an undue contraction of the compressor urethrae, and a want of consent between it and the expulsor muscles. I have never, however, in these cases (and I have seen many), found this spasmodic contraction give rise to strictures; the patient has either died from the intensity of the original injury, or the inflammation has been unequal to the production of stricture of a permanent kind, although capable of giving rise to a distressing temporary derangement of an inflammatory spasmodic nature. Irritation of the neck of the bladder in middle aged persons often occurs from an acrid state of the urine, but it does not in them give rise to stricture.

The common cause of stricture of any kind is gonorrhoea, when neglected and allowed to run on to the chronic state called gleet; and it is assuredly not the severity of the attack that does the mischief, but its long continuance, or its renewal after the most marked symptoms have subsided. In a regiment of young soldiers of a thousand men, few cases of stricture occur, although hundreds of them may in turn be affected by gonorrhoea. It is only when they become older, and do not choose to undergo the discipline of an hospital, but continue to drink, and do their duty, leaving the disease to itself, or to some nostrum common among them, that strictures occur. The idea which prevailed a few years ago with some surgeons of great repute, that it was best to do nothing, and allow the disease to subside of itself, under a regular and orderly course of living, was a fertile cause of stricture in many who supposed they carried the precept into execution. Astringent injections were supposed (and the opinion was at one time carefully inculcated) to have been a common cause of strictures, but I believe there was some misrepresentation in this, almost amounting to something more: for a long and great experience has con-

vinced me that it is not the use, but the abuse, of injections which does mischief, and precisely in the same manner, that doing nothing is the source of mischief. The one is the abuse of too much means, or an improper use of them, the other the abstaining from means of cure altogether; and I further maintain, that it does not signify in what way a gonorrhœa is cured, provided it is quickly cured. But I do not mean by cured, a state in which a greater defect, or another disease, is caused of a more troublesome character. That is not what I call a cure, but only an exchange of one disease for another of a more serious nature.

When a gonorrhœa or a gleet has given rise to positive alteration of structure, or of obstruction in the canal, the symptoms are sufficiently marked, according to the several states and stages of disease, and the discretion and judgment of the surgeon are more called for in the earlier than in the later stages of the complaint; for he may in the first, by doing too much, make that disease permanent, which is only temporary, which would be a great evil; whilst in the latter he can only do a little temporary mischief. In order to understand this, it is necessary to bear in mind that the range of disease, from an inflammation, or spasmodic stricture so called, to an obstinately permanent one, extends from a mere vascular thickening of the internal mucous membrane, and of the cellular tissue which attaches it to the external elastic wall of the canal, unto a thickening and alteration of them with a deprivation of their elasticity, and extending even into the corpus spongiosum, or surrounding parts.

A gleet, or muco-purulent, or nearly serous discharge from the urethra, unattended by pain in micturition, and only accompanied by it when the erectile tissue is dilated, may be caused by several states of the canal. The most common is a chronic, or sub-acute state of inflammation, almost degenerating into passive, affecting the mucous membrane and its subjacent cellular texture only. The next in order is where any, or several of the large follicles are dilated and diseased, a state which occurs most frequently about the fossa navicularis, or first inch and a half of the urethra; and, lastly, when ulceration takes place from either of these, or any other causes in the course of the urethra generally, from the external orifice to the neck of the bladder. The first state may exist for many months, and then gradually cease, and the parts be restored to their natural state, without leaving any mischief behind, although it very rarely does so, unless the habit of the patient's life has been temperate. I occasionally see some old friends of mine, whom I had under my care near thirty years ago, and who suffered in this manner for ten, twelve, and eighteen months, drinking all the time from one to three bottles of wine a day. They never have had strictures, nor have them now, but these are *rara aves*, and I could note a long catalogue of others who comported themselves in a similar way, who have long since been numbered

with the dead, or are suffering for their errors; and it is from the observation of a great number of these cases, and of the general results of the different kinds of treatment, that I am induced to say, cure your disease quickly, but cure it carefully and thoroughly, and it signifies not by what means. You will often find that what cures one person will have no effect on another.

The chronic state of inflammation, essentially constituting gleet, may be quite local, but it is frequently constitutional, and can only be cured by constitutional treatment; and it is not easy to decide when the constitutional treatment should entirely supersede the local, or be combined in a particular manner with it. It must be regulated by that tact which is obtained by good sense, founded on good teaching and on observation. When the patient is regular in his habits and apparently in high health, the distinction or discrimination becomes very difficult, and the practical result often belies the preconceived opinion. When a gonorrhœa has terminated at the end of three or four months in a thin watery discharge, which is scarcely perceptible at times, although easily brought on, and becoming considerable on a slight excess of any kind, there is a part of the passage in a chronic state of inflammation, which general treatment will rarely cure, and which local means, without great attention, will not reach; for it is rare that this low inflammation is confined to the specific distance of Mr. Hunter or the first two inches, but, on the contrary, more usually exists also in those parts in which it has been excited by sympathy, or by extension of inflammation, viz. the bulbous, the membranous, and the prostatic parts of the urethra. It becomes, therefore, advisable that the affected part should be ascertained by the bougie, which is also often the best means of cure; but it is a two-edged instrument, alike the means of health and safety, and of misery and long suffering. In the hands of a skilful surgeon, it is the harbinger of health, in those of a rough and violent one, it is the cause of disease. If there be a lesson which deserves and demands a most strict observance, it is that which inculcates gentleness, lightness of hand, and patience in the use of the bougie, as opposed to roughness, force, and haste. It is agreeable, sometimes, to pass a bougie readily where another has failed; it is flattering to self love to pass a larger one, and the patient himself often exults as well as his surgeon, but in the end he will have nothing to boast of, except, perhaps, a permanent stricture. The bougie, selected for an examination of this kind, should not exceed two-thirds of the size of the orifice, and should be passed along the canal until a sensation of pain is experienced, when its progress should cease; if there is little thickening, the pain will gradually subside, and the bougie may again be gently pressed on. If it now passes easily, and with little sensation, it is of a proper size to do good, but, if at the attempt to pass it, the pain is augmented, it

will generally do harm, and ought to be withdrawn, and a smaller one substituted on the next occasion, and so on, until one will proceed with little comparative inconvenience. It is in these cases that the first introduction of a bougie often causes the patient to faint; and to prevent his falling, and to enable them to act with vigour, sometimes a vigour beyond what the case requires, some surgeons place their patient's back against the wall. This you have seen I never do, because I take it to be a most butcher-like proceeding; but there is no disputing about taste, and some persons like that position, because, as they say they cannot flinch. For these cases a soft bougie is the best, it looks less formidable although it does not always pass the easiest. The pain is usually felt in the bulbous part of the urethra, if there be no disease anterior to it; and is usually described as a sharp pain, differing from the subsequent or burning sensation experienced on the bougie passing along the membranous and prostatic parts, and which is also accompanied by so strong a sensation of making water, that the patient says it is actually coming, and in some rare instances it does positively flow, although usually it is but a heightened sensation, and he sees to his surprise that it is so. It is now that he feels sick, turns pale, fancies a thick mist before his eyes, drops of perspiration stand on his forehead, and, if not assisted, he falls, even before he can ask for a chair or a glass of water. I always let a patient stand before me, and with an arm chair behind him, and, when I see these symptoms coming on, I seat him in the chair, and bend his head down until it touches his knees, which removes the faintness better than water or any cordial you can offer him. This faint feeling is hardly experienced a second time, and very rarely a third. I have known it, however, always recur on the introduction of a metallic bougie, but never on that of a soft one. The instrument should not in these cases be used more frequently than once every four days, and the size should be very slowly augmented. If the bougie meets on the second trial with a greater instead of a less obstacle, or gives more pain, its use must be desisted from for a time, and perhaps never resumed. If it be continued, the mischief will gradually increase, and at last a permanent stricture may be the result. The surgeon has, in fact, caused and kept up such repeated irritation, that the inflammation has extended into the adjacent elastic structures, and given rise to a greater evil than it was intended to cure. In these cases, leeches, the warm-bath, and other remedies, I shall frequently allude to for the cure of irritable urethra, must be had recourse to. The part often bleeds in such cases on the slightest touch, and will do so sometimes even when the bougie is doing good, not harm; but I have never found a bleeding of this kind mischievous; on the contrary, it seems to do good, by relieving the overloaded and excited vessels, so much so, that I think patients

usually say, after they have ceased to be alarmed by it, that they do not mind a little blood, as they always feel easier after it; an old sufferer invariably says so. A large bougie, carried forcibly through a urethra of this kind, sometimes cures, which appears paradoxical, but the fact is, that a great deal of irritation is excited of a new kind, and, under the means employed for its reduction, both that and the old irritation gradually diminish, and even actually disappear, leaving the part nearly in a state of health, and into which it ultimately passes; more often, however, a great and permanent accession of irritation is the result, extending even to the mucous lining of the bladder, and giving rise to great distress. An officer of dragoons, suffering from gleet, applied to a surgeon, saying he must leave town that day to join his regiment; on which the other replied, that he must then do something for him, and passed down a large bougie, which only went through with almost intolerable pain. The gentleman travelled the same night to his regiment by mail, was laid up for three months, and came back to town to put himself under my care, making his water every hour, which was loaded with one third part of mucopurulent matter resembling pure pus. It took three months more to remove the symptoms thus caused by the introduction of a bougie a little too violently. When the complaint is trifling, and the mucous membrane but little swelled or inflamed, the method of Bruninghausen, which consists in firmly closing the orifice of the urethra, by pressing the sides of it against each other, and then dilating the canal by attempting to make water, which is thus prevented from flowing, may do good in a similar way to the bougie, but it cannot, I conceive, be useful in cases of permanent stricture.

When the patient will submit to an examination of the part by the bougie, so that the seat of irritation may be ascertained, the cure can almost always be completed by it, provided the part is not very irritable or of great extent, or there is nothing peculiar in the constitution of the patient; in either of which cases it will not succeed, nor in some without other assistance, in which the bougie fills the canal without pain, yet the discharge still continues. A gentleman placed himself under my care some half a dozen years ago, on account of a gleet, for which he had consulted several persons in vain. On examining the urethra, I found he had such a very large one, that all my silver sounds were too small to fill it, I had therefore two steel ones made, Nos. 19 and 20, the last larger than my fore finger, and it was only when the canal was dilated, so as to be put a little on the stretch, that he was cured; but this was not done without the aid of an aluminous injection. This gentleman always laughs and gives me a nod of recognition when we meet in the streets, and I certainly have never seen such

perhaps, a similar

one might be found in one of the mummies at the College.

I cut off the arm of an officer of cavalry, in front of Fuente Guinaldo, in the year 1811, and met him in 1816, in Bond-street. He said he was under the care of the late Mr. Pearson, for a discharge and strictures, but would leave him if I wished, and come to me. I told him not to do so, but to stay where he was well off. He did so, and six weeks afterwards he called on me, to say that his urethra was perfectly sound, save the discharge, which was quite as much as ever, and that Mr. Pearson had recommended his taking the chalybeate Cheltenham waters. I advised him to obey orders like a good soldier. He did so, and, in the course of a month, as his health amended, his complaint disappeared. He calls on me now whenever he comes to town, to have a bougie passed, and occasionally, although one-armed, uses one himself.

A nobleman applied to me last year, on account of a discharge, which yielded tolerably easily to cubebs or to copaiba, or to a mixture of either, or of both, with the tinct. benzoës, comp., but as soon as they were omitted it returned, and injections fared the same fate. I did my best, but with no better success than my predecessors. I then recommended the bougie, but this he disliked, and went to Dublin, where he met with no better success. From thence he travelled on the continent, and was ultimately cured by the waters of Spa.

It often happens, that the same remedies, which have proved inefficient at one time, will render especial service at another, and the same may be said of injections. A gentleman applied to me under similar circumstances with the last, despairing of being cured, having, as he said, tried every means of stopping the discharge in vain. He had taken cubebs in the usual manner, with only temporary advantage, but by swallowing two drachm doses every two hours, when awake, for three days, it was at last permanently arrested, and he has lived to contract several other gonorrhœa, which have proved less obstinate; the successful method in this case is not, however, less fallacious than any other. In another case, of nearly similar character, the tinctura ferri murialis effected a cure, I believe, not from any specific influence on the urethra, but by amending the general health. Quinine acts in a similar manner.

When one spot only in the urethra is irritable, and resists the use of the bougie, however gentle the manner of introducing it, I am in the habit of making applications direct to the part. An ointment, composed of the *argentum nitratum*, *liq. plumbi subacet.*, and *ung. adipis suillæ*, in varied proportions from two grains to ten of the former to one drachm of the latter, is an admirable application. Its great efficacy in chronic inflammation of the

urethra, and I have reaped the greatest advantage from it in many very obstinate gleet, depending on chronic inflammation and thickening of the mucous membrane, even of the prostatic part of the urethra, where, by common consent of all British surgeons, no caustic in its solid form ought to be applied. Lead, opium, belladonna, used in a similar manner; the dregs of the *vinum opii* mixed with lard have all been useful in removing that degree of irritation which stimulants can alone control and subdue. These applications must all, however, be used with caution and judgment; in fact, they must be used but not abused.

When the urethra is generally irritable, I have not found them equally serviceable, and as this state seems to be materially dependent on the constitution of the individual, general means of cure are of more importance than local ones; indeed, the surgeon should abstain from them altogether; the urethra should never be touched, although remedies may be used externally, such as the mercurial or iodine ointments, or even blistering, or the *argentum nitratum*, applied so as to produce that effect.

The internal remedies I rely most on, in such cases, are mercury and hemlock, with rest and attention to diet and the state of the bowels; the occasional application of leeches and the hot-bath, followed by a change of air to the country, or the sea-side. I have never sent a patient, under such circumstances, on a tour up the Rhine that they have not returned quite well, provided there was no permanent stricture. The *pil. hydrargyri* I find the best preparation, in the proportion of from one to two grains three times a-day, with from three to ten grains of *extr. conii*. The effects of the one on the gums, and the other on the head and stomach must be carefully watched, and the remedies increased or diminished accordingly. When the patient has gone through a long course of saline and alkaline remedies without effect; when cubebs, and copaiba, and the *terebinthinæ* have failed, and bougies of every kind have only rendered the part and the patient more irritable; these remedies, and a change of air and scene, if only for a mile or two into the country, will often prove most efficacious. If a young man, with an irritable urethra, will go to dinners, balls, and the opera, and drink wine, and sit up until two in the morning, you had better wait until the season is over before you endeavour to cure him.

When the gleet is dependent on one or more excrescences in the urethra, their bleeding and the sensation communicated by the bougie will usually lead to the suspicion of their existence, and it will ultimately cure them; for, in such cases, internal medicine cannot I conceive, be of any avail. When from the pain being felt at one spot, and one spot only, or particularly, and which can be made manifest by external pressure, in the

first five or six inches of the urethra, and it does not yield to common means, although the bougie, of a full size, meets with little obstruction, it is probable an ulcer exists at that part, and the ung. argent. nitrat. will be of great service. I have had two cases lately under my care, in which a gleet discharge was attributed to a painful spot within the first inch of the passage; this increased, and the ulcer, luckily proceeding forwards, became visible, and at last affected even the orifice, with a very syphilitic aspect; the cure in both was effected by a gentle course of mercury, and a mild astringent injection.

Sir E. Home has delineated the follicular appearance of the urethra exceedingly well in one of his magnified engravings. Some of these follicles, as well in the fore as the back part of the urethra are large, and when affected by chronic disease become much more so, and resemble small cavities or sacs, in which a pea might be lodged, and in which the point of a bougie will often catch. In the prostatic part of the urethra, the ducts of the prostate will also give rise to a similar result, so that the stoppage of a bougie in this situation would often lead to the suspicion of stricture, and to much mischief if stricture were admitted to take place in this part. In the anterior portion, a larger solid bougie always rides over the spot where a smaller one has caught, and shows the error, which an impression taken on a soft bougie will prove; although the freedom with which the urine passes belies the possibility of a stricture to the extent of apparent obstruction. These follicles will often prove very intractable, particularly when situated just behind the glans penis, I find an injection of the solution of the argentum nitratum, of from six to twelve grains to the ounce of distilled water, one of the best remedies, as it can be made to enter the cavity of the follicle without difficulty. Sometimes the follicle does not enlarge at its orifice, but, on the contrary, the opening into the urethra seems to become smaller or to be positively closed up, whilst the inflammation continues in the cavity itself. Under these circumstances, the cavity enlarges, so as to be felt externally; and when this takes place, as it occasionally does, just behind the frænum præputii, it gives rise to a very troublesome disease. The little cavity being put on the stretch by the secretion poured out within, at last yields, I believe, by ulceration, and a portion of its contents are effused into the cellular structure between the two layers of skin forming the prepuce, and through the internal layer of which, near the frænum, or near the fold or edge, it at last finds its way, and one or two small sinuses are thus formed, which are more disagreeable than painful. A very fine lachrymal probe can be made to follow the course of these sinuses, which often communicate and lead to the original seat of evil. The first person I had occasion to treat, labouring under this

affection, was a lieutenant-colonel in the army, in the year 1816, who had two sinuses of the kind described, one on each side of the frænum. These I divided; then the frænum, then the outer wall of the urethra, which is here very thin, so that the cavity of the follicle was exposed; and when a solid sound was introduced into the canal, it seemed to be covered by the thinnest possible layer of membrane only. Under slight stimulants and astringent applications this gentleman got quite well. I have seen several cases of the kind since, which, as far as I recollect, have not attracted the attention of surgeons, writing professedly on these subjects. The last was of a neighbour of mine, residing in Cork-street, who, after a gonorrhœa, suffered from an inconvenience of this nature. He had applied to three surgeons of great reputation before he came to me; and had worn a silk thread, by way of a seton, in a double sinus for the last three months; this I removed, and then divided the sinuses in the prepuce down to the follicle; they healed in consequence, and removed all the inconvenience he laboured under, the prepuce about the frænum being only a little more moist than usual from the secretion from the follicle. He says himself that he is quite well and cured of his disease. Instead of the enlarged follicle yielding and discharging itself externally in this manner, it sometimes increases in size, and by pressure can be made to empty itself into the urethra, which it does in less quantity at all times, and thus keeps up an interminable discharge. When ulceration has taken place in the orifice, so as to enlarge it, instead of diminish it, as in the previous instances, the urine gets into and distends it on every attempt to make water. Pressure of the finger, on such occasions, and the use of mild stimulants and injections, will frequently give rise to the diminution of the swelling, and the cessation of the discharge; but if the swelling should increase, and threaten to inflame, and burst externally, the surgeon should anticipate this process by opening it, so as to have sound instead of ulcerated external parts, and then endeavour by stimulants, such as the red precipitate, or the green digestive ointment, or the argentum nitratum, alternated with the sulphate of copper, to induce it to heal from the bottom. I have seen every effort, however, fail, and a permanent small opening has been the result, requiring the pressure of the finger upon it every time the individual passed his water. When a follicular gland of this kind becomes hardened, and shows no sign of alteration, it may be left to nature, but sometimes, in addition to the hardness which can be felt by pressing the corpus spongiosum between the finger and thumb, a secretion takes place from it keeping up a gleet discharge, accompanied by irritation, and occasional chordees, which render the patient very uncomfortable. Nature does little, and stimulants do less in these cases. From the ung. hydr. c. camph. I have de-

gives considerable advantage, provided it is long continued, and at length a cure will be effected, if the patient will be regular and continue its use for a sufficient length of time. I have also seen much good follow the application of a blister, and where all other things have failed, pressure made by introducing a moderate sized catheter into the bladder, and then by strapping around that part of the penis with sticking plaster. The catheter should not be too large, or it will produce irritation, neither should the adhesive plaster be applied too tight. The patient must be kept quiet, and in bed or on the sofa, and on any irritation supervening, the process must be for a time suspended. Sometimes these swellings, or tumours resembling them, dwindle away into small indurations, which become almost of a cartilaginous hardness, the erectile tissue in which they are situated appears to have lost its natural property, and whilst every other part is fully distended, this remains a small hard tumour. In some cases it is absorbed, leaving however a hardness, which does not admit of the part being dilated, and causes a hollow in it, when the rest of the erectile tissue is distended. I have seen the same thing take place in the corpora cavernosa, when they become more or less crooked, on dilatation taking place, and the part, in some rare instances, seems to be changed into bone.

OBSERVATIONS ON THE USE OF BLISTERS IN BUBOES, AND OF TINCTURE OF IODINE COMPRESSES IN HYDROCELE.

BY P. RICORD, D. M. P.,

Surgeon of the Hôpital des Vénériens, &c.

TRANSLATED BY ALEX. THOMSON, M.D. OF ST. JOHN'S, CAMBRIDGE.

From the Journal des Connaissances Médico-Chirurgicales, for January, 1834.

Of Blisters in the Treatment of Buboes.

BLISTERS have been used in the treatment of buboes, but all practitioners are not agreed upon the precise circumstances indicating them, and which we shall endeavour to develop, in an ensuing article upon this subject. M. Renaud, doctor of medicine, and a distinguished professor of Toulon, has recently proposed, in a work presented to the Academy of Medicine, the employment of the blister in all or almost all the cases of buboes, without distinction of period or duration. From the explanations, which he himself had the kindness to give me, when he did me the honour to visit my clinical service at the Hôpital des Vénériens, I have employed his method, which consists in placing upon the buboes a blister,

which on the next day is dressed with linen ravelings, soaked in a solution of the deuto-chloride of mercury, twenty grains to an ounce of water, and the following are the results I have obtained.

In twenty-three patients affected with syphilitic buboes, or those deemed to be such, fifteen were not yet arrived at the period of suppuration, and eight were already suppurated, the skin more or less attenuated, and the purulent collection united into an abscess.

Of the first fifteen patients, seven have been obliged to have successive blisters, the solution of the corrosive sublimate not having at all kept up the suppuration of the skin. Of this number six have been cured without suppuration; and, by a resolution, arriving more speedily than by the ordinary means. In one, the suppuration supervened, and it was necessary to open it; the other eight had blisters; two have been cured by resolution; six have opened spontaneously, of which two did with a vast separation of the skin.

In the eight patients in whom the buboes had already suppurated, and who had equally had blisters placed according to the method of M. Renaud, two have been cured, without their buboes having opened, the pus having been little by little re-absorbed, and the skin at the surface of the blisters having presented that sort of purulent transpiration indicated by M. Renaud. In the other six, after spontaneous apertures, and a great separation of the attenuated skin, it has been necessary to have recourse to the caustic potass or to the bistoury.

These results that we present here in mass, and without precisising the cases, since the author of this method applies it to all, have not given us the same results as to him; for M. Renaud has told us that, with the blister, spontaneous apertures of the buboes are very rare, and that more rarely still, has he been obliged to have recourse to artificial apertures.

Without participating entirely in the opinion of my brother, our results have been different. I think that the blister, applied in suitable circumstances, and which we shall hereafter appreciate, is a powerful means in the treatment of buboes.

Employment of the Tincture of Iodine for the cure of Hydrocele.

Cases of hydrocele, independent of any syphilitic cause, frequently present themselves

in my ward; and I have already been able to employ, in five patients, a new means in the treatment of this affection, and one which has furnished me happy results; this means is the tincture of iodine, diluted with distilled water, and applied upon the tumour by aid of compresses imbued with it, and in which the scrotum is enveloped. The different degrees of concentration, in which I have employed it, are the following:

Take of
Tincture of iodine, 1 drachm } \oplus by weight,
Distilled water, 3 ounces } Fr. measure.
Mix them.

Tincture of iodine, 2 drachms } \oplus ditto.
Distilled water, 3 ounces }
Mix them.

Tincture of iodine, 3 drachms } \oplus ditto.
Distilled water, 3 ounces }
Mix them.

Tincture of iodine, 6 drachms } \oplus ditto.
Distilled water, 3 ounces }
Mix them.

In a subject whose skin is very delicate, and the epidermis thin, the first formula suffices. When there is less sensibility and some hardness of the tissues, it is passed on successively to the other formulæ. For the medicine to act, the patients must experience a rather vivid, but supportable sensation of heat, and without there being burning or vesication, the skin of the scrotum must become brown, or pass into brownish red, the epidermis becoming *like parchment*, and forming scales, that are detached, leaving beneath them a sort of thick transpiration still without vesication. So long as these results be not obtained the dose of the tincture of iodine must be increased, the quantity of distilled water remaining the same; but when these effects have been succeeded in being produced, the same degree of concentration of the tincture must be continued by renewing, twice a day, the compresses steeped in it. If pain supervenes, it is suspended for some days, and resumed subsequently, until the disappearance of the tumour.

The following cases, drawn up by M. Rattier, and collected in my service, will show the advantageous results of this method of treatment.

Jean Gouttel has been for nine years back affected with a hydrocele of the left side, of which the formation had been preceded by an orchitis, the result of a blow on the testicle.

The tumour has remained stationary up to the present day, 5th Oct.: its bulk equals that of a large turkey's egg; the tunica vaginalis appears distended with more force than usually; but no symptom of inflammation is remarked.

M. Ricord ordered the use of the tincture of iodine at two drachms. Until the 4th day the action of the medicine is little marked; on the 6th the epidermis is detached in brownish scales, and abundant transpiration is produced; on the 7th the tumour is much less tense,—there is formed upon the scrotum a sort of dry and blackish pellicle. On the 15th Oct., new exfoliation, the scrotum is very humid, the tumour is diminished in bulk,—it is no more than one-third of its primitive size; the solution is carried to three drachms. The phenomena we have indicated are reproduced regularly until the 2nd of November, and the patient goes out cured. M. Ricord has again seen Gouttel on the 23rd November, and the cure has appeared to be radical.

To this observation we shall add those we have already published in the *Gazette des Hopitaux*, and equally drawn up in the clinical service of M. Ricord.

Pierre Verger, fourth ward, No. 14, affected with an incysted hydrocele of the cord, has been cured, after fifteen days' treatment, by the use of the tincture of iodine, employed at first during five days at a twenty-fourth, and the following days at a twelfth.

Claude Cardot, first ward, No. 4. This patient has been perfectly cured of a hydrocele, of a considerable bulk, in thirty-six days. During the first fifteen days, the solution of the tincture of iodine at two drachms was employed, and afterwards at three drachms.

Jacques Fauché, first ward, No. 29, for the radical cure of a hydrocele, complicated with induration of the testicle; it has required thirty-five days' treatment, during the first ten the solution was at two drachms.

Delorme, first ward, No. 18. In this patient the treatment has been long, but in some measure proportionate to the bulk of the hydrocele; the solution of two drachms has been employed during thirty days nearly, and during twenty days, the solution at three drachms.

Errata in Mr. Thomson's Paper on Tubercles, in No. 98, Vol. IV.

Page 624, col. 2, lines 31 and 32, for "more

abundantly than from the walls of the envelope generally; though this was also the case, all doubt," &c., read "more abundantly than from the wall of the envelope generally, though this was also the case. All doubt," &c.

- Line 46, same page and col., *for* "who have spent so much of their lives in attempting to prove theoretically, that tubercle differs from other morbid growths *neither* in its essential *nor* organic structure," read "who have spent so much of their lives in attempting to prove theoretically, that tubercle differs from other morbid growths *by* its essential *non-organic* structure."

Foreign Medicine.

Method adopted by M. Roux to restore the Perineum in cases of division, or complete Rupture.

THE plan recommended by this surgeon is the same as that employed in cases of hare-lip; that is to say, after having pared, with a cutting instrument, the cicatrised borders of the ruptured part, he approximates the edges, and keeps them in contact, by means of the twisted suture. M. Roux thinks that the numerous failures in this operation have been caused by not keeping the internal edges of the wound in contact, and thus allowing of the entrance of fluid between the lips, which would naturally tend to prevent adhesion; it was, then, with the intention of remedying this, that he has made use of the twisted suture, and with such success, that, out of four cases of old rupture, three have been followed by complete cure; in the fourth case, the circumstances under which the operation was performed were so extremely unfavourable, that the patient died. The first performance of the operation was, in the first instance, only partially successful; for some weeks an opening in the deep part of the perineum existed, which, however, afterwards closed. This female has since been delivered of a child, without any rupture or other ill consequences.

Galvanism against the Poison of the Viper and Serpent.

M. Pravas lately read a paper before the Academy of Medicine, relative to the employment of galvanism against the poisons of the viper and serpent. In 1831, M. Breschet

sent to him the vesicles of many of the serpents of India, collected in the four preceding years; with a lancet, he opened that of the coluber major; the virus was yellow and acid, and reddened tincture of turnsole; a pigeon, whose thigh was inoculated with it, died in a little time, with the ordinary symptoms of this poison. At Altorf, in the year 1830, four dogs were inoculated with rabid virus of this kind, one of them was then submitted to the action of a galvanic pile four hours after, and was cured; in the three other instances the galvanic pile was not applied, and the animals died in about fifty-three hours.

In March, 1833, out of four dogs thus inoculated, two were galvanised, and recovered, the others were not treated in this way, and died in a rabid state.

The Phosphorescent Fungus growing in the South of France.

It is not, we believe, generally known, that there is found growing in the south of France a species of the fungus tribe, which emits a phosphorescent light at the period when decay commences. The inferior lamellated face is the only part which possesses this peculiar property, and as this is turned downwards, it is only the reflection on the ground at night which can be perceived; no particular odour accompanies this luminous appearance, which is inherent in the tissue of the lamellated structure, and which is perceptible in the smallest portion, even when separated from the rest; friction, however, destroys by degrees this property. Experiments have been made with the microscope, both in the day and the night, upon this class, but no difference in structure between the part endowed with this phosphorescent property, and that which is not, has hitherto been discovered. It appears, then, that the luminous phenomena manifest the greatest activity in the reproductive organs, and an activity, which is transient in vegetables and animals, is commonly marked by increase of colour or odour, but rarely, as in this case, by phosphorescent qualities.

Since the fructification of some of the fungi takes place with a phosphoric light, may we not attach more credit to the assertion of Beaufort, who says that, from one of the species of African flowers, a flame escapes at the moment of its blooming? The phosphoric

appearance, which was probably the real state, might with ease be exaggerated into a flame, by any one who saw with the eyes of a traveller.—*Gazette Médicale*.

Physiological Considerations upon the Organ of Hearing.

BY M. G. BRESCHET.

In a valuable memoir on the above subject, lately presented to the Royal Academy of Sciences in Paris, the author says, that, from the anatomical consideration published in a preceding memoir, it would appear that the vestibule is the most important part of the labyrinth, being in truth the proper organ of hearing; and that all the other parts are only accessories. Audition, considered in this manner, belongs exclusively to the vestibule and semicircular canals,—it is, in fact, to these parts that the organ of hearing is reduced in the entire class of vertebrated animals. In fishes, the ampullæ of the semicircular canals are very voluminous, the tubes long, and the median sinus very large. The sac, of which the existence has been proved in man, and at least suspected in mammiferous animals, is large, and well marked in fishes. In the cartilaginous fishes, the difference in size between the semicircular canals and the other parts of the labyrinth is much more remarkable than in the mammiferous tribe; a considerable space exists between the cartilaginous walls and the exterior surface of the labyrinth, which is occupied by the perilymph; in many of the bony fishes, however, the membranous labyrinth is only suspended on the inside of the bones of the cranium, and is filled with a liquid which appears to be analogous to the humour of cotugno, found in the semicircular canal in man, the mammiferous tribes, birds, and reptiles. After entering into a minute account of the structure of the component parts of the ear in fishes, which our limits will not allow of extracting, M. Breschet remarks, that the analogy of structure between the ear and the eye is very remarkable; thus we find in each organ three media traversed, in the one by rays of light, in the other by sound. In the ear we find a liquid, called the perilymph, enclosed in the vestibule, as in the eye we find the aqueous humour, contained in the first space; in the ear also there is a second fluid, called the vitrine, enclosed in a small membranous apparatus, upon the

walls of which expand the nervous chords, in a similar manner to the expansion of the optic nerve around the vitreous humour of the eye. The oolithes or the octoconies resemble also in situation the crystalline lens. There are, perhaps then, two kinds of impression produced on the ear by sounds; first, the impression which is made upon the lamina spiralis of the cochlea; second, that which operates upon the sac, and the ampullæ of the semicircular canals. The small disc of the stapes, corresponding to the fenestra ovalis, instead of transmitting sounds directly to the acoustic nerve, spreading out on the membrane, transmits only the sonorous vibrations to the liquid of cotugno or perilymph. The two liquids, by which the cavities of the labyrinth are occupied, appear to multiply the points of contact of the acoustic nerve with the vibrating body, to render the excitement more lively, and to augment for this purpose the vibratory faculty of the membrane of the sac; the experiments of M. Savart show, in fact, that any tissue or paper, moistened, conveys vibrations with greater facility than when dry. Sounds are transmitted to the labyrinth in the greater portion of fishes only by osseous or cartilaginous walls; and this mode of transmission would, perhaps, be less advantageous than that performed by means of the cavity of the tympanum filled with air; and, by an osseous chain, put in motion by the vibrations of the external air, if these animals lived in the air; but they inhabit a medium more dense; and we are disposed to consider this mode of transmission through solid walls more advantageous by such a medium.

Observations on Intermittent Fever.

All intermittent fevers, according to M. Roche, depend on one and the same cause: whether they arise in the midst of a morass, upon the banks of rivers, in the midst of a great town, or in a country considered healthy, they all depend on the contact of miasma with the nervous centres. If fevers, then, are the consequence of the introduction into the economy of a particular miasm, they are, according to the author, caused neither by inflammation, nor by affection of the nerves, but by the admission of poison. The proof, according to him, lies in the period of the cold fit, the hot stage, and the perspiration, which represent, as it were, in miniature, the phases of in-

toxication. Each paroxysm is not, as we might expect, a fresh entrance of the poison, since the paroxysms often continue long after the malady has quitted the nidus of infection; but these paroxysms are repeated, even until the elimination of the miasma introduced into the economy is complete. The interval between two paroxysms is the maturing of the poisonous miasma, to which succeed the eliminatory efforts, which occur so frequently, that the morbid agent is not completely expelled. The author considers the administration of quinine only beneficial, because it possesses the property of neutralising this miasma. This, then, is the antidote in intermittent fevers, and the bleedings, vomitings, purgatives, and sudorifics, which sometimes arrest the paroxysm, act only by the elimination of the morbid agent.

The following list of suicides, committed in London between the years 1770 and 1830, has been extracted from the *Gazette Médicale de Paris*.

Indication of Causes.	Men.	Women.

We read in the *Dorfzeitung*, that the homœopathic system has received a severe blow at Vienna. The physicians, practising according to this doctrine, have been visited by the police, the medicines have been seized, and the whole of the homœopathic pharmacy has been suppressed. Many of the inhabitants, favourable to this mode of practice, have determined upon petitioning the Emperor, that they may be permitted to live and die homœopathically.

MEETING OF THE MEDICAL PROFESSION AT LIVERPOOL.

On Wednesday last a public meeting of the profession was held at the Medical Library, in accordance with a resolution of the Medical Society. There were about one hundred medical men present. Dr. Rutten was called to the Chair.

Mr. McCulloch (honorary surgeon to the workhouse) called the attention of the meeting to certain remarks made by Mr. G. Rogerson, at a late meeting of the Medical Society, and which the *Lancet* had copied from the local papers. He then read the passage as follows:

"In Liverpool, talent is not the standard; abilities are not the passport to their public offices. The sons, nephews, or even the grandmothers (*a laugh*) of a locally influential character, would be elected in preference to a Hunter. Relationship, matrimonial alliances, and commercial connexions, are the heads of this medical hydra."

He then animadverted on what he called the injustice of those remarks. It had been said, that the sons, nephews, or even grandmothers of a locally influential character would be elected in preference to a Hunter.

Dr. Anderson here said, that this discussion was out of order.

The Chairman assented, and called Mr. McCulloch to order.

Dr. Collins.—Let the gentleman have rope enough, and he'll hang himself. (*A laugh*.)

Dr. Lane then moved the first resolution (seconded by Mr. G. Rogerson,) to the effect, that "the partial and restrictive distribution of privileges, legalised by the different charters at present possessed by the various colleges throughout Great Britain,—the numerous sources of medical licences—the discordant and, in some instances, imperfect systems of professional education allowed by universities,—the extremely defective preliminary classical education of great numbers of young men now introduced into the profession,—the insufficient proof of competency, upon which individuals may gain legal permission to practise the art and science of medicine,—the exclusion of persons (already recognised by British medical incorporations as duly qualified to exercise the healing art) from practising physic in particular districts,—the im-

proper interference of the apothecaries' act with the rights of well-educated physicians and surgeons every where, but particularly in rural districts, to prepare and compound medicines for their own patients—the non-protection afforded to legitimate practitioners against collision with uneducated empirics—the tacit permission given to quacks and all unqualified persons to exercise the functions of educated members of the profession—and the fact so universally prevalent, of druggists prescribing medicines, to the danger of his Majesty's subjects, as well as the disadvantage and prejudice of those legally authorised, are circumstances which, in the opinion of this meeting, evidence the imperfections of the laws of the medical profession, and prove the necessity of legislative interference."

The resolution, as originally proposed, contained an allusion to the power (rarely exercised, we believe,) of the bishops to confer medical degrees, and was omitted, from respect to the clergy, and in the hope that the coming change in the church would remove the grievance.

Dr. Jeffrey objected to the clause relating to the druggists, as he did not wish any particular class of persons to be pointedly alluded to, and they would be generally included in the term "unqualified persons."

Dr. Collins suggested, that the druggists should be mentioned, for the fact was well known, that they actually did prescribe, as if they were qualified.

The clause was retained, every one, except Dr. Jeffrey, being in favour of its reception.

Dr. Collins then suggested the propriety of introducing a clause to the effect, that medical remunerations should be legalised.

The Chairman said, that this had been in contemplation, but was left to the Committee. Physician suffered much from the advantages now taken of their peculiar situation in this respect. He himself had lost much money on this account.

A Committee of seven was then appointed to draw up a petition embodying the spirit of the first resolution. They are to correspond with the Medical Associations of London, and to adopt such measures as it may seem requisite for the assurance of an amelioration of the state of the medical profession. The following gentlemen were named on the Committee:—Dr. Rutter, Mr. Geo. Rogerson, Dr. Jeffrey,

Mr. Christian, Dr. Lane, Dr. Macintyre, and Mr. Van Oven.

The meeting then adjourned, after a vote of thanks had been given to the Chairman.

IMPORTANT DECISION TO THE MEDICAL PROFESSION, GLASGOW.

This was an action brought by an assignee or mandatory, for a surgeon in town against a husband, for payment of an account for medicine and attendance on his wife. The defence was non-liability, in respect that, for about three years previous to the contraction of the account, the parties had lived separately (the wife having, since that period, as was alleged, been living in open adultery), that he had inhibited her, and that he had been paying her an alimony suitable to his circumstances. The defender produced receipts from the wife to the amount of 15*l.*, and it was not proved that she had received more than that sum from him during the whole time they had been living apart. On the other hand, it was admitted and proved for the pursuer, that, at the period of the surgeon's attendance, and subsequently, the defender had been calling on and cohabiting with his wife, and pleaded that this did away with the defence arising from the fact of separation; that the inhibition only applied to extravagant and unnecessary contractions; and that, as to the alimony paid, it was not sufficient to support her during the period of separation; and besides, that the circumstance of paying alimony did not affect the peculiar claim founded on. The Justices, however, held, that the surgeon was bound to proceed against the wife, and dismissed the action *in hoc statu*.

STATE OF GENERAL PRACTITIONERS IN THE COUNTRY.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—I take the liberty of addressing this to you, first, as editors of a most excellent work, the *London Medical and Surgical Journal*, and, secondly, as friends to Medical Reform, that the inroads now made in the Medical Profession may be entirely removed, and the General Practitioner may again hold that situation in life, which his forefathers held with so much credit to themselves,

in times that are past. I live, gentlemen, in a large market town in the west of England, where, forty years ago, there was no such thing as a druggist in the place; there are now now no less than four, and three out of the four visit patients, prescribe for them in their shops, bleed, draw teeth, and attend fractured limbs, depriving the regular medical practitioner of more than half of his practice. Now, gentlemen, not one of these has had any regular medical education whatever. One served his apprenticeship in this town to a general practitioner, went afterwards to Bristol, and became assistant to an apothecary; he then came into this town, without attending either the London or any provincial medical schools, set up for himself as a druggist and apothecary, and is now in possession of freehold houses, and, by encroaching upon the practice of the general practitioner, is absolutely making more money in the year, by his so doing, than the general practitioner who has spent a little fortune in regularly attending the London hospitals. The second came here only as an assistant to a general practitioner, a few years ago, married a wife, and is now attending, when called upon, to all the duties of a general practitioner. The third is a new one, not having resided here more than twelve months, but who is now following in the steps of the other two, without any more pretensions to a medical education than either of the others. The consequence, now, gentlemen, is that the whole of the practice of three of us is not equal to what was formerly done by one, when druggists were unknown in this town; and if something is not done, the regular practitioner must yield the palm to the uneducated druggist. I am sorry thus, gentlemen, to trouble you with this, but knowing that your wish to see the regular practitioner righted is becoming more and more evident to the medical profession, I trust any further apology will be unnecessary.

I am, Gentlemen,

Yours, most respectfully,

R. BAILLY, Surgeon.

West Gloucestershire,

January, 1834.

P. S.—I am a very constant reader and admirer of your valuable Journal, and therefore shall look forward with pleasure to your noticing this communication in a future number.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, February 1st, 1834.

DR. GREGORY, President, in the Chair.

Diseases of the Heart.

THE preliminary business having been transacted,

A member related a case of disease of the heart, which was considered aneurism of the aorta. In addition to the symptoms generally present, there was a violent, and periodical pain in the pyloric region of the stomach. On examination of the body after death, there was found fluid in the cavity of the pleura, hypertrophy of the heart, adhesion of the pericardium, and ossification of the mitral valves, but nothing which, in his opinion, accounted satisfactorily for the pain in the epigastrium.

Dr. Johnson said that a great many cases were considered aneurism of the aorta, when nothing more than hypertrophy was found after death; it was only where a specific pulsation was felt in the upper part of the chest, and where absorption of the ribs had taken place, that he in general made up his mind as to the existence of aneurism of this part.

The gentleman who had related the case said, that Dr. Elliotson (by whom it had been considered aneurism) had stated that there was much difficulty in distinguishing this aortic disease; but, from the sounds elicited by the stethoscope, he had, in this instance, certainly considered it as a case of this nature. He had mentioned the case, as he was anxious to know if the pain in the stomach in such cases had been observed by other gentlemen.

Mr. Smith mentioned a somewhat similar instance, marked by symptoms of dropsy in the chest, and violent pain in the stomach, with general anasarca; extensive ossification of the mitral valves was found. (A preparation, exhibiting this diseased state of the valves, was exhibited to the Society.) He wished to know if Dr. Johnson had met with many specimens of disease of the valves.

Dr. Johnson said that he did not think that disease of the mitral valves was so rare as was sometimes supposed. He had been consulted in the case of a young gentleman,

who had a most extraordinary enlargement of the heart; the pulsation was very violent, and the bruit de soufflet was heard with the greatest distinctness; the sound of the blood rushing through the heart was also very evident. Some time since he became universally dropsical; the urine was scanty, and he was troubled with dyspnoea to a great extent; he appeared at the point of death, but by the use of elaterium and mercury, so as to affect the gums, the fluid has been repeatedly carried off, with the exception of some small quantity in the chest, and he has been so much relieved, that to casual observers he really now appears in good health. With respect to the pain in the stomach mentioned, he did not think that it was a common symptom in diseased heart, but it was probable that the close connexion of the pericardium with the tendinous portion of the diaphragm was the cause. Frequently there were pains in various parts of the body in organic disease of the heart, which could not be accounted for, for instance, in the shoulder or over the os pubis; it was, he thought, therefore better, in estimating the general symptoms of a disease, to consider such as were not usually found as merely accidental. In treating this disease, he had found that no remedy had proved so useful as keeping the system under the influence of mercury for some weeks.

Dr. Gregory had met with a case, where a gentleman, much accustomed to boxing and other violent exercises, had over exerted himself; he was seized with violent pain in the biceps muscle of the arm, which became greatly enlarged, and very painful. He (Dr. Gregory) considered that in the same way hypertrophy of the heart was to be attributed to increase of size from increased action rather than to any other cause.

Mr. Costello believed, that the enlargement mentioned in the muscle was not very uncommon, and was caused by its escape from the sheath; at the same time he acknowledged the justice of the conclusion drawn by Dr. Gregory.

Mr. Hunt thought it strange that it should be supposed, that the increased action of the heart would cause increase in the substance of that organ. Those who were accustomed to examine cases of this kind must have found the fibres lax, and diminished rather than increased in size.

Mr. Smith did not think that it was the substance of the heart which was affected in metastasis of rheumatism to that part; it appeared to him, that, as it was generally in rheumatism of the fibrous structures that this metastasis took place, it also was the fibrous structure of the pericardium which was affected.

Mr. Hunt differed from the last speaker as to the part affected. He had never found the pericardium, in inflammatory rheumatism, in the least degree connected with the inflammation. It was, in his opinion, rather in the interstitial than the muscular substance of the heart that the disease was found to be situated.

Dr. Aldis imagined metastasis to be an extension along the fibrous structure. He then spoke as to the efficacy of bleeding in this form of complaint, and stated, that, in some cases combined with dropsy at St. George's Hospital, tinct. of cantharides had been used with benefit.

Dr. Stewart wished to know, if Mr. Costello, who had made some experiments upon the blood in cases similar to those under consideration, had ever given iodine after mercury; he himself had with much advantage used this remedy, and had nearly come to the conclusion, that as blood-letting formed the ground work for other remedies, so mercury formed the foundation for the use of iodine; he merely, however, mentioned this as a hint for further experiments, for he was not prepared to state positively that such was the fact.

Dr. Johnson had found the conjunction of these two remedies advantageous; there were very few diseases in which iodine was useful, where small doses of mercury might not also be given with advantage.

A patient, on whom Mr. Costello had successfully performed the operation of lithotomy, was exhibited to the Society.

Notice was then given, that on Saturday next Mr. Costello would bring forward the subject of Torsion of Arteries, after which the meeting separated.

MEDICAL SOCIETY OF LONDON.

Monday, February 3, 1831.

W. KINGDON, Esq., President, in the Chair.

Distension of the Gall Bladder from Obstruction in the Duct—Use and Abuse of Tea and Coffee.

In continuance of the debate at the last meet-

ing on deleterious rice, some remarks were made by Dr. Tyler and some other members on the subject, after which

Mr. Jones exhibited to the society an enlarged gall bladder, taken by him from a boy, æt. 9, who died comatose. Upon examination, this viscus was found extending into the right iliac region, and contained about three quarters of a pint of bile; the duct was impervious, but the obstruction appeared to be caused by enlarged glands pressing upon it, for on its being removed from the body, the biliary secretion flowed through it with facility; the circumstance of glands, causing obstruction, was not, however, peculiar to these ducts, for the passage of fluids through other channels was sometimes impeded by the same cause; he had observed this in the veins of the thigh in scrofulous subjects, and had noticed that frequently only the one side of the body was affected.

Mr. Kingdon remarked, that sometimes the passage through much larger tubes than the ductus communis choledochus was closed by this kind of pressure, for a case had fallen under his observation, where the colon was tied down by the mesocolon, which, together with some enlarged glands, rendered it quite impervious.

Mr. Cole then read a paper on the symptoms and noxious effects produced by the excessive use of the infusion of tea and coffee. He stated that when either of these were taken in large quantities, they acted in the first instance as decided, and powerful stimulants, acting principally upon the sanguiferous and nervous systems, banishing the necessity for sleep, and producing feelings of exhilaration; this state was, however, quickly followed by palpitations of the heart, irregular and oppressed respiration, and distressing sensations in the region of the præcordia; the pulse became irregular and feeble, the extremities cold, and pains and gnawing sensations in the stomach were felt; attacks of syncope rapidly succeeded; a desire for sleep now made its appearance, but the slumbers of the patient were troubled and uneasy, and spasmodic action of the limbs took place. It appears that those, who had once suffered from the use of these vegetable substances, were only relieved by abstaining entirely from them; he had observed that green tea excited a more powerful effect than either the other kind or coffee, the latter of which was the next in

order in its powers; from the observation of the symptoms caused by these articles of common use, it became a question whether their introduction into this country was not the cause of some of the diseases of the heart now so commonly found. Twenty-two cases, proving the injurious and deleterious effects of the articles under consideration, were attached to this paper, some of the most important of which were read to the meeting.

One or two members, from their own experience, testified to the truth of the preceding observations, after which the Society separated.

THE
London Medical & Surgical Journal
Saturday, February 8, 1834.

MEDICAL JOURNALISM.—NOTICE OF
PARLIAMENTARY INQUIRY.

It is generally the policy of a journal to set itself up as the advocate of this or that party; and, by a devoted attachment to its interests, by respecting or lauding its prejudices, by denying or palliating its defects, and, above all, by heaping opprobrium upon the antagonist faction, to earn an interested support. Of the nature of this exaggerated advocacy in state politics, the public is so well aware, that none but the most violent adopt the opinions, or credit the unauthorised statements of a newspaper on either side; and yet the rational inquirer may form a very tolerable estimate of the real facts, or a very just opinion upon them, after consulting such discordant authorities. We knew an excellent gentleman, who used to say, he found the Court Circular of great value in forming a correct judgment of the state of Foreign Politics.

Even in medical journalism this spirit of party, with its usual consequences, is strongly predominant; and, although it is our main object, in common with our weekly contemporaries, to place before the profession an early account of the most

recent observations, and the most instructive lectures, (and, as to our success herein, we fear no comparison;) still, in our strictures upon the condition of the profession, in the material points of education, of rank, and of legal right,—we are conscious there is a wide difference between us and our two contemporaries. To what party, then, do we attach ourselves? Between Scylla and Charybdis, is it possible to steer a straight-forward course? It would be idle for us to dictate to others, how we may have succeeded in our efforts on the agitated subject of medical reform:—but of our motives and objects we are the best judges. We neither labour to uphold an insolent aristocracy, founded upon pretensions foreign to medical science; nor do we assert the claims of every man just qualified to pass the lightest of our medical examinations, to be ranked, upon such an estimate of professional acquirements, on a level with the *dignitaries* of the profession. We are desirous to abolish all artificial distinctions of practitioners: and, in order to entitle every practitioner in medicine to assume the same legal rank, we require an uniform education from every member of the profession. Let the general practitioner be in future a *physician*, or a *doctor*, if the name rejoices him more, but let him also have the physician's education.

“What!” some adroit sophist who pretends to the patronage of the general practitioners will exclaim; “What! you libel the general practitioners: you insist upon the inadequacy of their examination!”—A word or two will silence for ever this crafty insinuation. In the first place, we talk not of the *present* race of general practitioners.—Their rights are vested by law; and, if we could, we would not injure one of them through the temptation of any public good in

prospect.—So much for the *least* qualified member of the profession, who has already just acquired a right to practise. But, again, we are well assured that amongst the present race of medical practitioners are to be found many men of varied and profound experience in medicine, who, by long and close application, and with every facility for extensive practice which their peculiar situation affords, have acquired that better education, which no curriculum, however improved, can guarantee to a student. On such persons who have already acquired the practical honours of their profession—many of them men of first-rate talent—we would willingly bestow at once the legal dignity of the profession. They have more than supplied the deficiencies of early education: we mean—let us not be misunderstood—the education which is *demanded*; for, without doubt, many have exceeded the legal bounds through pure shame of tampering with life, upon the modicum of knowledge at present required at the Halls of Lincoln's-Inn-Fields, or Blackfriars. These respectable practitioners, whose studies have kept pace with the advance of medical science, are unanimous in desiring a reform of the system of medical education; as none are better judges of the solemn responsibility of a medical adviser, whose deeds, whether for good or evil, are worked in secrecy. The public can form but a very inaccurate judgment of his success or failure. We mean not, then, to libel the present race of general practitioners, in advocating the necessity of an enlarged education for the future. The charge would be too ridiculous, were there not a selfish motive at the bottom, which makes it as disgusting as it is unfair.—The rights of all must be preserved—their true rank must be accorded to many. But there is

nothing to prevent our guarding against the occurrence of the mischiefs admitted to exist, by the introduction of a general and simple plan of elementary education, to be pursued by every student who hereafter seeks a diploma to practise.

We believe we have the full concurrence of the respectable portion of the general practitioners in other opinions commonly advocated in this Journal, touching that part of the profession: and that they are most anxiously desirous to be placed in "a position," to use the words of a cutting contemporary, "which would render professional trickery a less tempting adjunct to medical practice." It is moonshine to talk of the respectability of trade.—Who ever doubted it? The question is, are two situations compatible?—A public contractor is a very lucrative, and, for aught we know to the contrary, a very respectable office: and yet the law says he shall not sit in Parliament, because of the danger of temptation. Such regulations may be libels on human nature; and in the same sense are we libellers, in advocating the necessity of separating the duties of a medical practitioner called upon to advise, from his interests as a vender of medicine, profiting by their sale,—and, as is frequently the case, looking to that profit for the remuneration of his advice!

The general practitioner has a great advantage, both in the way of emolument, and of early practice, over the physician, by the smallness of his charges—John Bull loves small charges. Some say he would not pay for the advice;—he expects that gratis, and he pays for the pill. We cannot—we do not believe, he is so senseless; or if he is so narrow-minded, it is the duty of the enlightened to eradicate the vulgar prejudice. Perhaps the transition to a more reasonable state of things cannot be instantaneous, or ever

perfect. But the feeling, if any such there be, exists, we believe, in the lower classes of the community only; and we are certain the middle classes would receive with satisfaction, the tidings that professional visits were, for the future, to be paid for at a moderate rate; and we see no reason to limit the scale. There is, after all, a principle of justice; and the services of a medical man are felt so sensibly, that he may, on the average, trust to the gratitude of his patients, that they will reward him according to their means; but, at the same time, the law should recognise his right to recover a proper remuneration, without the humbug of the *honorarium quiddam*.

We have touched upon some of the leading doctrines of this Journal, by which we desire to be distinguished; while we do not disregard the co-operation of others upon purposes of public utility. The time is at hand when principles are to be tried. Mr. Warburton has given earnest that he will, at an early opportunity, redeem his pledge of instituting a parliamentary inquiry into the state of the profession. The honourable member gave notice, on the first day of the meeting of Parliament, that he would, on an early occasion, move for a committee to inquire into the state of the medical and anatomical schools. The first blow is half the battle. It has broken down the guard of the Corporations;—they are stunned; they are minuted; they may give a convulsive struggle, but the victory is sure.

Reviews.

The Principles and Practice of Obstetric Medicine, in a Series of Systematic Dissertations on Midwifery, and on the Diseases of Women and Children. Illustrated by numerous Plates. By D. D. DAVIS, M.D., M.R.S.L., Professor of Midwife-

in the University of London, &c. 4th. Part xxviii. London, Feb., 1834.

We have frequently expressed our high approval of this valuable production, and are happy to observe, that the number before us is one of the best we have seen. It is devoted to disorganisations and polypi of the uterus, and is enriched by the result of the author's great experience, and that of others. The learned Professor has long enjoyed the most extensive opportunities of treating diseases of women; and his acquaintance with continental works on the subject is evidently very extensive. One so qualified cannot fail to execute a work of sterling value. This production, considering its value and cheapness, deserves encouragement, and we understand has a large circulation, which it well merits.

A Series of Anatomical Plates, in Lithography, with References and Physiological Comments, illustrating the Structure of the different parts of the Human Body. Edited by JONES QUAIN, M.D., Professor of Anatomy in the University of London. J. Taylor. Folio. Plates 6 and 7.

This truly excellent work appears regularly, and continues to gain a rapid circulation. There are few more competent to execute it, than the eloquent and justly popular editor. We should strongly advise our junior friends to possess it, both on account of its moderate price, and its extreme value. The work is highly creditable to Professor Quain and to the institution to which he belongs.

On the Influence of Minute Doses of Mercury, combined with Appropriate Treatment of various Diseases, in restoring the functions of Health, and the principles on which it depends. By A. P. WILSON PH.D., M.D., F.R.S. London, 1834. 12mo. H. Renshaw.

The object of this little work is to prove the great efficacy of minute doses of mercury in chronic diseases. The celebrated author assures us, that his observations are the result of thirty years' experience. He commences with a description of the *modus operandi* of mercury; and makes many instructive statements, proving that the liver is much more frequently the cause of dyspeptic and other

complaints than is generally imagined. He maintains that the quantity of mercury, given in this country, is ten times greater than that from which its most beneficial effects would accrue. He alludes to the mischief done by excessive salivation, and the immense benefit derived from the small quantity prescribed by Mr. Abernethy. Dr. Philip successfully proves, that small doses, even the one-twelfth or one-twentieth of a grain, will be prescribed with the greatest benefit. His account of the action of mercury on the body will be perused with advantage by every class of our readers.

A Synopsis of Systematic Botany, as connected with the Plants admitted into the Pharmacopœias of London, Edinburgh, and Dublin; accompanied by a Planisphere, showing at one View the Class and Order of the Medical Genera according to Linnaeus and Jussieu. By THOMAS CASTLE, M.D., F.L.S., &c. &c. 4to. pp. 18. London 1833. E. Cox, Borough.

There is no science, perhaps, so diligently cultivated by a large portion of the community, as that of botany. The great facilities for its investigation render it more peculiarly attractive than any other branch of Natural Philosophy. To the medical student it presents a field of interesting inquiry, and to him, at least, an acquaintance with those plants that are known to possess curative virtues is indispensably necessary; but it is greatly desirable that his attention and research should not end here. There are, undoubtedly, many plants whose sanative qualities have not been discovered, or sufficiently attended to. A diligent consideration and a studious investigation of the natural affinities and relationships of the vegetable tribes would contribute, in no small degree, towards supplying this desideratum; for it is generally admitted, that those plants which agree in structure, organisation, and mode of growth, are often found to correspond in their medical properties.

To eulogise the labours of the great Linnaeus, which have received the homage of all civilised nations and ranks, would be superfluous; his Sexual System will probably never be surpassed in simplicity and comprehensiveness. It gives a clear, well-defined, and admirable outline of the family of Flora; at the same time, simple and grand, and generally harmonious; but there is a discrepancy in

some of the parts—the inevitable consequence of viewing the mighty panorama of nature in a single light, however luminous or broad that light may be. This defect has called forth the efforts of many talented individuals in order to find a remedy. The illustrious Swede himself was aware of this, and he accordingly framed his Natural System. To what degree he succeeded it is not our province to determine: it is, perhaps, more ingenious than practically useful; for, though founded on a consideration of several striking peculiarities, common to many individuals, it has not a few of the failings that attend his Artificial System, without the peculiar beauties of the latter.

Among Natural Methods, that of Jussieu holds a high rank, and deservedly so too. The system established by De Candolle seems to be the chief competitor with it for superiority; but that of Jussieu, as modified and improved by later botanists, offers greater advantages and facilities to the young botanist, on account of its less abstruse and less complicated character.

But these remarks were more immediately elicited by a work on Medical Botany, by Dr. Castle, entitled “A Synopsis,” &c., which is well worth the attention of the inquiring student. It contains, in the first place, a *Planisphere*, elegantly conceived and neatly executed, exhibiting at once the class and order of every plant that enters the three *Pharmacopœias*, according to the Linnæan Sexual System, and the Natural Methods of Linnæus and Jussieu. To this is added a concise and luminous exposition of each system, showing the number of plants belonging to every order, their time of flowering, native country, and different synonyms. It comprises, in small compass, a large portion of information on the subject of which it treats, which must otherwise be sought for in ponderous volumes, with no small expenditure of time and patience; and, in conclusion, we recommend it as well calculated to serve as an auxiliary to the interesting and important science of which it gives a limited yet valuable sketch.

A Compendium of Osteology being a Systematic Treatise on the Bones of the Human Body, designed for the use of Students. To which is subjoined an Improved

Method of Preparing Bones for Osteological Purposes. By GEORGE WITT, M.D., Physician to the General Infirmary, Bedford. 4to. 1834. Longman and Co.

The confused appearance of the numerous parts, described in an osteological lecture, is sufficient to deter any one from attempting to establish any thing like a regular method or order, in impressing them on the memory; the author of this compendium has attempted it, and we cannot but think it has been accomplished in the most perfect and complete manner, of which the nature of the subject admits; it is evident, also, throughout every page of the work, that the greatest pains and labour have been bestowed upon it, and in every respect it appears extremely well calculated to answer its purpose. It is stated in the preface, that the plan has stood the test of some years' experience, and we are glad that the author has thus satisfied himself and his pupils of its utility, previously to undertaking the cost and trouble of publishing such a work; it is neatly printed, and its price is moderate; probably it will be generally adopted as an anatomical class book, as it has already been spoken of in the highest terms by several lecturers on anatomy.

The parts of each bone are described consecutively, exactly as they are brought into view by holding the bone in a particular position, and turning it as upon a given axis; the description is arranged in a tabular form, and every point connected with each part is contained, generally, in a single line, so that the memory more readily and more perfectly retains the impression of parts thus *read off*, in this lucid order and succession; the advantages of this simple plan, it is said in the preface, can hardly be imagined without actual experiment.

A series of questions is added to each division of the book, and they are so studiously and carefully written as to comprise all that has been, or ought to have been, learned of the preceding subjects; they are indeed very cleverly contrived to *prove* the degree of success which has attended a student's labour.

The author has also directed his attention to the annoying difficulty and uncertainty which attend the preparation of bones; how imperfectly and unsuccessfully the process of maceration is generally conducted, is shown too

plainly in our museums; but it has at last been brought to satisfactory and successful principles; the bones thus prepared are perfectly white, and not a particle of grease is visible in any one of them. No secret has ever been made of his plan, and, at the request of his friends, the author has been induced to make it generally known by adding it in an appendix to his book; the directions are so minute and explicit, that we shall hope for the future to see none but the most perfectly prepared bones in our collections.

We deem it our duty to make so truly creditable and useful a work as much known as possible to our readers, and we are persuaded that both the junior and senior members of the profession will warmly approve the opinion we have given of its merits. It is an extremely valuable work to the student and teacher of anatomy.

French Hospital Reports.

HÔPITAL DU MIDI.

Serous Cyst in the Abdomen communicating with the Intestines.—Cyst of the same kind in the Scrotum.

A. B. was admitted into the hospital, under M. Ricord, for a tumour in the left testicle, which had existed eight months. It was about four inches long and three broad, and had, at its inferior part, a distinct hard portion, which corresponded in size to the healthy testicle. Apparently there was fluctuation in the part, and from this and other signs M. Ricord was inclined to believe that hydrocele was present; accordingly a puncture was made with a trocar, but no fluid escaped. A tumour, still more obscure in its character, existed in the abdomen, but, although the sensation of fluctuation was also evident, no fluid followed the introduction of a trocar; the opening, however, ulcerated, and from it sprouted a cancerous fungus. Suddenly the abdominal tumour disappeared, and the general symptoms, which had become serious, diminished in intensity. Amputation of the testicle was accordingly performed, but the patient sunk soon after the operation, and died.

The scrotal tumour consisted of a number of serous cysts, varying from the size of a pea to that of a walnut; one of these was as large

as a hen's egg; the remainder of the tumour consisted of a cancerous structure. In the abdomen was found the tumour which was supposed gone, and which was an oval sac containing fluid; the intestine communicated with this sac by a round opening, at least two inches in diameter, with black looking ulcerated edges.

Œsophagus terminating in a Cul de Sac at the border of the second Dorsal Vertebrae.

An infant, strong, and well formed externally, was observed by Dr. Mondiere to pass a great quantity of mucus by the nostrils, and to emit a peculiar noise from the throat soon after birth. During the first night of its existence, it voided a great quantity of urine, and meconium, and these evacuations continued for the remainder of its life, which lasted only five days.

All the thoracic and abdominal viscera were in a healthy state, with the exception of the stomach and œsophagus. This last terminated in a cul de sac, at the level of the second dorsal vertebrae; from this point, for the space of seven or eight lines below, the canal was replaced by a fibro-cellular chord, after which it again became normal. The great cul de sac of the stomach was entirely wanting, and in its situation was a large opening, of which the edges did not present either traces of ulceration or softening.

HÔTEL DIEU DE TROYES.

Leaves of the Birch Tree (Betula alba) in Chronic Rheumatism.

A. R. had been subject to frequent attacks of chronic rheumatism, which had left swelling and stiffness in his knees and feet; treatment of different kinds, such as baths, fumigations, &c., had been used without any success in removing these symptoms; the patient, having heard that the leaves of the birch tree had proved of service in some cases, procured a bag, sufficiently long to extend from the toes to the middle of the thighs, and having filled it with fresh birch leaves, completely free from humidity, inserted his feet and legs into the sack on going to bed, a profuse perspiration was caused, and the stiffness was thereby much relieved; encouraged by the success, he persevered in his remedy, and in a short time he was perfectly well. M. Augustein of Cologne,

to whom this was related, has since tried the same remedy, with perfect success, in cases where baths of different kinds had in vain been previously used.—*Russ's Magazine.*

Aneurism, with thinning of the right cavities of the Heart—membranous partition situated at the commencement of the Pulmonary Artery, and perforated in the centre—Hypertrophy of the Liver.

BY DR. FALLOT,

Chief Physician to the Belgian Army.

M. N., ætat. 63, residing in Brussels, but a German by birth, has been subject, since the cessation of the menstrual discharge, at the age of 47, to dyspnœa and shortness of breath. The heart beats tumultuously, but the pulse is regular, although hard and vibrating. In the right hypochondrium there is a hard tumour in the situation of the liver. The only remedy by which any relief is afforded is bleeding, which has been frequently practised. Towards the end of February, 1833, she was seized with violent pains in the region of the heart, and with frequent attacks of vertigo. Her respiration became more embarrassed, and she was unable to stand. Towards the month of June she became delirious, and on the 16th expired in great agony.

Autopsy.—The heart was found to weigh fourteen ounces and a quarter; by its excessive development it had pushed the mediastinum into the right cavity of the thorax. The right auricle and ventricle, and two venæ cavæ, were much enlarged; and, in consequence of the dilatation of the cavities on this side, the tricuspid valve did not near close the auriculo-ventricular opening. The walls, also, of this portion were softened and much thinned, but were covered by a thick lamina of coagulum, composed of different coloured strata, and partially enveloping the columnæ carneæ. In place of the semilunar valves of the pulmonary artery, a thick membrane attached to the circumference of the orifice of this artery was found: its concavity, which was directed towards the ventricle, was pierced at its centre with an opening about the size of a goose-quill. The free and attached borders were thicker than the rest of the membrane. The left cavities of the heart were of the natural size, and were perfectly healthy. The tissue

of the lungs was much compressed by the enlargement of the heart, but was permeable to air. The tumour in the hypochondrium proved to be the liver greatly increased in size. This gland, and the whole system of abdominal veins were found gorged with blood.

Admission of Air into a Vein during an Operation, followed by death.

In operating on a patient for cancer of the breast, and induration of the glands in the axilla, Dr. Goulard, of Lyons, wounded a large vein, from which a little blood escaped. At the same instant convulsive movements of the extremities took place. Hiccup succeeded, and in a few minutes the woman expired. No examination of the body was made.

British Hospital Reports.

ST. THOMAS'S HOSPITAL.

Anæmia.

JOSEPH FLETCHER, æt. 44, admitted October 25th, 1832, under the care of Dr. Elliotson. Has been a clerk in a mercantile house, but, owing to some misfortune, is obliged to gain his livelihood by mangling; has lately lived in a cellar, the air of which is foul and unhealthy; was suffering from jaundice five months ago, and was a patient in St. Bartholomew's Hospital; appears at present to be convalescent from a severe attack; conjunctiva and countenance yellowish; bowels open; pain on pressing over the liver, which is enlarged; tongue white and moist; lips and gums quite pale; mouth clammy; on moving about feels sick, and complains of dizziness in the head; ankles œdematous; great weakness; slight bruit de soufflet; has great desire for acidulated food. Ordered acid. sulph. dilut. ℥ xx. Decoc. cinchon. ter die.

30th. Complains of throbbing in the head. Ordered ung. iodinae regioni hepatis; hydr. submur. gr. ij, o. n.; lactis Oj, quotidie.

Nov. 2nd. Omitt. pilul. et mistura. Cap. ferri subcarb. ʒij, ter die. V.S. ad. ʒij. The bleeding ordered with the view of ascertaining the quality of the blood.

9th. The slightest force broke down the crassamentum, and the quantity of serum was great in proportion.

On the 6th, the subcarbonate of iron was increased to ʒij, every four hours.

13th. On the 9th he was ordered meat and a pint of porter daily. Is gaining strength; appetite improved; still complains of throbbing in the head; pulse 120, and sharp.

20th. Is troubled with hæmorrhoids, for which ung. gallæ comp. has been applied; appetite good; feels stronger; throbbing of head better; the icterode hue of the surface

still remains. Ordered lot. alumin. ano; lactis Oij, quotidie; vin. rubr. ℥iv, quotidie.

23rd. Is not so well; complains of great pain on pressing over the liver; pulse 100, small and sharp; thirsty.

24th. Is much worse; great pain on pressing over the region of the liver, as also over the loins; great thirst; continually moaning, and bewailing on his wretched condition; at times incoherent; has not passed any urine since early this morning, and that high coloured; pulse 124, very sharp; skin hot. Ordered to leave off his wine, iron ointment, and meat. Applic. empl. canth. regioni hepatis.

25th. Much worse; breathing difficult; delirious muttering.

27th. Died early this morning, and the post-mortem examination took place in the afternoon.

A small quantity of fluid was found under the dura mater; the brain bloodless, but in other respects healthy; the heart and lungs very pale, and the former very flaccid; the liver enlarged, but the structure appeared healthy, although bloodless, as were the whole of the viscera.

Elizabeth Watson, æt. 26, a servant, admitted Nov. 17th, under the care of Dr. Elliotson. Has been ill for the last five months; complains of palpitation of the heart, and fainting on taking the least exercise; swimming in the head, and headach; loud bellows sound; menstruated a fortnight ago, but very scantily; countenance pale and yellowish; ankles swollen; bowels open; tongue clean.—Ordered ferri carbon. ʒij., ter. die.

14th. States that there appears to be sparks of fire flying about her; is menstruating; the discharge pale and scanty; still great giddiness, &c.

21th. Has rather more colour, and less dizziness of the head; since the 19th has taken ʒss of the ferri carb.

Dec. 3rd. Less palpitation of the heart; headach better; countenance not so pale.

10th. Menstruated on the 7th, the discharge redder; appetite better; oedema of legs less.

15th. Bellows sound not so loud as on her admittance; oedema of ankles entirely subsided; countenance and tongue have more colour.

18th. Bellows sound hardly perceptible even on lying down; no swimming or dizziness of the head.

19th. Discharged.

Elizabeth Holdsworth, æt. 23, dressmaker, admitted November 7th, under the care of Dr. Elliotson. Has been ill two months; complains of palpitation at times; swimming of the head; and also of bearing down pain in the inguinal region; bellows sound, with the pulse about the middle of sternum; has not menstruated for the last six weeks; the catamenia have always been irregular, and of a

pale colour; appetite bad; tongue pale; conjunctiva blueish; bowels confined; pulse 80, soft; sense of suffocation. Ordered ferri carbon. ʒij. ter. die.; extr. coloc. c. gr. v. o. n.

14th. No pain or dizziness of the head; menstruating; the discharge pale coloured.

22nd. Has been suffering from cramps in the legs. Ferri carb. increased to ʒss on the 19th.

27th. Has more colour; appetite better; bowels open; bellows sound still continues.

Dec. 3rd. Has considerably more colour; the conjunctiva has lost its blueness.

10th. Menstruated on the 7th; the discharge redder; less bellows sound; appetite good; no oedema of legs.

15th. No swimming of the head; more colour in the face; bowels regular; but some bellows sound still continues.

19th. Discharged.

MIDDLESEX HOSPITAL.

Diseases of the Larynx.

Considerable attention has of late been directed to affections of the larynx and its neighbouring parts, while many of the important diseases have been omitted in the older authors. Numerous cases have recently found their way into the medical journals, where sudden death has occurred from disease going on in the respiratory tube. Sudden death has taken place, and acute inflammation been found involving the pharynx, larynx, and trachea, in other instances a small ulcer on the epiglottis has been detected; in others again there has been effusion in the sub-mucous cellular tissue; and the cases are not wanting where nothing morbid has been seen. In the latter, the cause of death is referred to spasm of the small muscles about the parts; but this spasm is not so readily accounted for. It is easy enough to explain why spasm should take place when inflammation, ulceration, or effusion exists, for here is something tangible which we cannot bring to our assistance when the whole apparatus is found healthy.

The theory of spasm, however, is objected to by some; yet where is the difficulty, when the subject is studied anatomically and physiologically? The glottis is possessed of a peculiar vitality, it is exquisitely sensible to any foreign matter, it acts harmoniously with every effort of respiration and inspiration, and is called into spasmodic action when a particle of food, however small, attempts to enter it.

Where, then, is the surprise that the larynx, apart endowed with a high degree of sensibility, and so actively engaged in the functions of respiration, should be the cause of death by spasmodic action? Such is the case; and the man dies as suddenly as though the medulla oblongata were divided.

It has been said that death is caused by the gradual narrowing of the passage, and consequent interruption of the oxygenation of the blood. This, doubtless, may be the case where

death is not sudden, but not at all applicable when it is so.

"It is not," as has been beautifully explained by Sir C. Bell, "that actual obstruction takes place if ulceration ensue, or the deposition even of coagulable lymph that causes death, but it is that the muscles are spasmodically excited."

The following case, as illustrative of the foregoing remarks, will be of interest to your readers:—

Isaac Clark, æt. 20, admitted into the hospital, Dec. 13, complaining of sore throat of three days' standing, swelling of the whole neck, throbbing of the temples, and general uneasiness; tongue white; skin hot; pulse frequent. Complains also of great difficulty in swallowing. Tonsils considerably swelled; no ulceration.

Hirudines xij. gutturi.

Pil. calomel. c. ant. 1 6tis.

14. Great relief from the leeches; feels altogether better. Has taken some bread and milk, and experienced less difficulty in swallowing. Rep. pil.

15. Throbbing of the temples; heat of skin greater; pulse full; no increase in the size of the tonsils; swallows with difficulty.

V.S. ad $\frac{3}{4}$ xij. Rep. pil.

Inhalat. vapor. aquæ calid.

16. Better this morning; no difficulty of breathing.

After the apothecary had gone round the hospital, he was suddenly summoned to this patient, whom he found in a state of suffocation.

After using the inhaler he seemed suddenly to choke, the face becoming livid, and breathing spasmodically. The jugular vein was opened, and the operation for laryngotomy performed by one of the surgeons, and artificial respiration attempted, but without any success. It was observed that the heart was pulsating strongly against the ribs when respiration had ceased for some time.

Post-mortem examination.—The only morbid appearances found were in the pharynx, larynx, and lungs. The pharynx was thickened in its walls, the membrane around being soft and infiltrated. The left tonsil, on being incised, exuded white clear pus. The epiglottis on the upper surface was thicker than natural, soft, and infiltrated, and presenting the appearance termed œdema. This was also evident in the mucous membrane between the epiglottis and the rima glottidis, but not sufficient to cause obstruction. The other parts of the larynx perfectly healthy. No inflammation here or in the trachea. Lungs crepitant and healthy, but gorged with blood.

Thus it appears there was no evidence of inflammation in the larynx, save effusion in the cellular membrane; at least there was no redness or effusion of lymph. Inflammation must have existed in the pharynx from the post mortem during life, and the purulent secretion found after death. Therefore it must be said

that the man died in consequence of the natural action of the part being altered, the integrity of which is necessary for every moment of existence.

WESTMINSTER HOSPITAL.

Fracture of the Neck of the Thigh Bone.

A WOMAN, æt. 60, of very robust frame, was admitted into the hospital some time since, having met with an accident, which occasioned the following symptoms. Immediately after she received the injury, she was completely deprived of the power of locomotion. There was a slight shortening of the broken limb (this is caused by the very powerful action of the muscles which draw up the lower part of the fracture), and the knee was somewhat curved. A crepitus was heard on making a rotatory motion, and there was eversion of the toes.

Mr. White, in calling the attention of the pupils to this case, remarked, that the position of the patient was unexceptionably excellent. The double inclined plane was the best machine in such cases, as it afforded most comfort to the patient, and permitted the posture to be easy. Mr. White added, that no hospital in London equalled the Westminster in their mode of adjusting fractures. They had arrived at a perfection in that branch of the profession which was universally allowed.

The perfect ease of position, and various other circumstances connected with the general health of this patient, almost permit us to expect a very favourable result to this case.

BOOKS.

A SERIES of Anatomical Plates, in Lithography; with References and Physiological Comments, illustrating the Structure of the Human Body. Edited by JONES QUAIN, M.D., Professor of Anatomy in the University of London. Fasciculi VII., VIII. Folio. London: February, 1834. John Taylor.

The Principles and Practice of Obstetric Medicine, in a Series of Systematic Dissertations on Midwifery, and on the Diseases of Women and Children. Illustrated by numerous Plates. By D. D. DAVIS, M.D., M.R.S.L., Professor of Midwifery in the University of London, &c. Part XXVIII. London: February, 1834. John Taylor.

The Animal Kingdom, arranged according to its Organisation; serving as a Foundation for the Natural History of Animals, and an Introduction to Comparative Anatomy. By BARON CUVIER. With additional Notes, and illustrated by nearly 500 additional Plates. Part II. London: 1834. G. Henderson, Old Bailey.

A Treatise on the Circulation of the Blood. Part I. contains—An Explication of the Anomalies, Res inepta, &c. of the Present Doctrine. Part II. An Attempt to explain how the Circulation of the Blood is accomplished by Motive Powers, different to those which are supposed to effect that operation. By J. F. HANDLEY. London: 1834. Longman and Co.

CORRESPONDENTS.

A Friend.—We are always ready to insert provincial hospital reports.

Edinensis.—We shall notice the pamphlet on the decline of the Edinburgh School of Medicine, at our earliest convenience.

A Fellow of the Medical Society.—The petition of the Society is, we believe, ready for signatures.

D. H. M..—The lectures are acceptable; but as we are now giving elementary courses, it is necessary to continue them regularly. The space for our third lecture has many claimants, each of whom shall receive our best attention.

A. T..—Some of the papers sent would occupy our entire number, and a quarterly contemporary declines accepting them; we shall turn them to account when convenience admits. We take this opportunity of requesting our numerous contributors to keep their communications as concise as possible, for otherwise we cannot insert them; even the quarterly journals decline them.

Gracchus.—Many thanks for the information.

Mr. Dermott.—Our reply to a correspondent in our last, had no reference whatever to Mr. Dermott, and we must decline noticing his correspondence in another journal.

Mr. Salmon's reply to Dr. O'Beirne, in our next.

A Constant Friend will observe we have acted upon his suggestion.

Crito.—Who cares a bawbee about the squabbles?

E. M..—Many thanks for the extracts.

A Reformer.—It is the unanimous wish of all respectable general practitioners, that remuneration should be received in fees; that medicine should be supplied gratuitously, and prepared by the prescriber, to secure its efficacy, and that open shops with quack medicines should be abolished. This was the opinion expressed at the Westminster Medical Society on a late occasion. There is no doubt but this plan, long since urged by that talented and eminent general practitioner, Mr. Cooke, of Trinity-square, would increase the respectability of the profession. The junior members might keep open shops, without vending chemicals, or quack medicines, perfumery, &c., and they should do so on commencing their career, to secure a practice.

LECTURES
ON THE
PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,
BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXVI., DELIVERED MARCH 27, 1833.

GENTLEMEN,—We now come to the consideration of the specific disease *melanosis*, or *black cancer*, as it is called by Baron Dupuytren, the *melanoma* of Professor Carswell, which is characterised by the formation of a brownish or deep black inorganic matter in various textures and cavities of the body, especially those lined by a serous membrane. The shades of its colour vary in different examples; sometimes presenting only a yellowish or light brown; sometimes a dark brown; and frequently the deepest black. It is to the celebrated pathologist Laennec, that we are indebted for the first published description of the disease; though Dupuytren maintains that he himself first brought it under the notice of the profession, in his Surgical Lectures, delivered prior to the time of Laennec's observations; and on this point a warm controversy arose between these eminent men.

The scientific arrangement of melanotic diseases, adopted by Professor Carswell, is, I think, most calculated to give you a correct idea of their principal varieties. He divides melanosis into the *true* and *spurious*; the first comprising those cases in which the formations or products depend on a change taking place in that process of secretion, whence the natural colour of certain parts of the body is derived; the second, comprehending cases in which either a carbonaceous matter has been introduced from without, or in which the appearances are owing to the action of chemical agents on the blood, or to the stagnation of the latter fluid.

According to Professor Carswell, the most frequent seat of *true melanosis* is the serous tissue, more especially where this constitutes

the cellular element of organs. Here the melanotic matter is formed after the manner of *secretion*, accumulates in the cells of which the serous tissue is composed, and gradually acquires the form of tumours of various sizes. A similar mode of formation of this matter takes place much more conspicuously in loose cellular tissue, and particularly on extensive serous surfaces, like those of the pleura and peritoneum. There is another mode of formation pointed out by Dr. Carswell: the melanotic matter is deposited in the substance, or molecular structure of organs, after the manner of *nutrition*. And lastly, as he has further explained, the melanotic matter is formed in the blood, chiefly in the venous capillaries, and under circumstances which show that it must have been formed in these vessels.

The valuable researches of Dr. Carswell, respecting melanosis, bring before us not less than four modifications of the true form of the disease.

1. The *punctiform melanosis*, in which the black colouring matter appears in the shape of minute points or dots, either grouped together in a small space, or scattered irregularly over a considerable extent of surface. These appearances are most frequently exhibited in the liver, and, when a section is made of it, the surface seems as if it had been sprinkled with soot or coal dust.

2. Another modification of true melanosis is what Dr. Carswell has named the *tuberciform*, and it is by far the most common one. Sometimes the tumour is not larger than a millet seed, but occasionally it is equal in bulk to a child's head, or even of more considerable dimensions. Of this size, however, they are chiefly seen in the horse; for you will rarely meet with an instance in the human body of the tumour exceeding the size of an egg or an orange, and commonly it is much smaller. It is in the loose cellular and adipose tissues that melanotic tumours are disposed to attain extraordinary magnitude. Their great size seems to depend upon the agglomeration of numerous small tumours. It is observed, likewise, by Dr. Carswell, that when the tumour is single, it is always of a globular or ovoid shape; but in the contrary circumstance it is lobulated.

In compound tissues, he has found it to be most frequently a *single* tumour, and in the cellular and adipose tissues, *aggregated*. In the liver, however, he has noticed that single melanotic tumours of large size are more common than in any other organ of compound structure.

Then, gentlemen, it is worth your while to remember, that melanotic tumours may be either *encysted* or *without a cyst*; and that the encysted ones are chiefly met with in the cellular and adipose tissues. The *tuberiform* melanosis of Professor Carswell, however, is not confined to the cellular and adipose tissues, or parts abounding in them; but may occur on the surface of the peritoneum, or that of the pleura.

3. Then, gentlemen, a third modification of true melanosis is described by Dr. Carswell under the name of *stratiform* melanosis, which occurs only on the surface of serous membranes. In its first stage, the part seems merely stained with the melanotic matter; in the second, a distinct layer of this substance is deposited on the surface of the serous membrane. Its consistence is generally that of jelly; and, as it is enclosed either in a soft spongy cellular tissue, or fine transparent serous membrane of new formation, it has a pulpy feel, but is not removed by the finger or scalpel passed over it, unless some force is employed. In certain cases, it forms a black coating, in appearance very much like what is produced by Indian ink.

4. The *liquiform* melanosis, the last of Dr. Carswell's species of true melanosis, may occur in natural or accidental cavities, and also within a melanotic tumour itself, in consequence of what French pathologists describe as the *softening process* in the centre. The cavities of the pleura and peritoneum are the chief natural cavities, in which the *liquiform melanosis* presents itself, and here only in small quantity. What has been described as this form of melanosis in mucous cavities, seems to Dr. Carswell to be owing to the changed colour of the blood, either effused in such cavities, or contained in its proper vessels, and acted upon by some external chemical agent, consequently they are spurious cases. It is in ovarian cysts that you will meet with the best examples of *accidental cavities*, in which *liquiform melanosis* is sometimes seen. The *consistence* of melanosis is exceedingly diversified. In the large cavities, it is never solid; in the cellular and adipose tissues, one or two cells may contain liquid black matter; but in the dense texture of the cutis, the smallest tumour may, according to Dr. Carswell's description, be as hard as cartilage.

The *spurious forms* of melanosis depend upon the introduction of carbonaceous matter into the pulmonary tissue in the process of respiration, or upon the action of acids, or other chemical agents on the blood, situated in, or upon parts; or lastly, upon the simple stagnation of this fluid.

Melanosis frequently originates in the subcutaneous cellular tissue, or in the cellular and adipose membrane, behind the peritoneum.

The most striking example of its circumscribed existence in adipose tissue, is that specified by Dr. Carswell, namely, where the disease occurs in the *appendiculæ epiploicæ*, which are sometimes converted by it into a homogeneous solid mass of melanotic matter.

Melanosis may take place in various parts of the same individual, as the eye, the skin, the liver, the lungs, the heart, the pancreas, and the peritoneal covering of the viscera. In this respect, the disease has a resemblance to fungus hæmatodes.

On the table, gentlemen, you see preparations illustrating the appearances of melanosis in the liver and lungs; in one, the sooty appearance of the surface of the section of the liver is finely exemplified.

The bones are not often the seat of melanosis. In one example, described by Dr. Alison, the whole of the sternum, the anterior portion of the ribs, and a great part of the parietal and occipital bones were black, more brittle, and of a softer consistence than natural, but without enlargement or caries. The periosteum was but little changed. In the same case, the dura mater was stained black, and the pleura studded with very dark coloured tubercles.

One interesting fact, explained by Professor Carswell, is, that the fluid of melanosis may be found in natural or artificial cavities, *without its being the product of their secretion*. This happens when melanotic tumours perforate the sides of those cavities, and pour their fluid contents into them. This has been observed in the thorax and abdomen; and in one case, a melanotic tumour had perforated the right lateral ventricle of the brain, in which was found a considerable quantity of black fluid, which afterwards passed into the third and fourth ventricles, and thence into the theca vertebralis.

Melanosis of the brain is rare. Here is a specimen of a small melanotic formation on the cerebellum of a child, that lived only three days from its birth. No doubt, therefore, in this instance the disease must have commenced in the foetus.

The matter of true melanosis has no smell, a circumstance by which the disease may always be known from the effects of gangrene.

With respect to the symptoms of melanosis in the living subject, the disease may at first produce little or no pain; but it is remarked, that a sallow complexion, excessive debility, and anasarca, frequently come on before its termination. In some instances, however, great general indisposition, and most severe pain in various parts of the body, were experienced from the first, and occasionally the patient is rapidly destroyed in the short space of three or four weeks. In common examples, I believe, it does not cause a vast deal of suffering, except when nerves are involved in it, or

compressed by it. The symptoms of melanosis in internal deep seated parts are very obscure. I attended a gentleman in the King's Bench, whose pulse was seldom more than thirty two or thirty-six. He was obliged to sit up a great part of the night, as when he went to bed he was sure to be attacked with something like angina pectoris. His appetite was good, and the alvine evacuations denoted nothing very wrong about the digestive organs. One morning he was found lying upon his face, perfectly dead. On opening the body, we found ossification of the mitral valves, a small calculus in the pelvis of one of the kidneys, and the whole liver enormously enlarged, and converted into a melanotic mass, of a purplish-black ink colour.

The matter of melanosis is completely insensible; it is only an inorganic secretion, or deposit, sometimes produced in textures, or upon surfaces otherwise apparently healthy and natural; sometimes produced in parts affected with chronic inflammation; and sometimes co-existent in the same mass, with either scirrhus, cancer, or fungus hæmatodes; a point, in which the researches of Professor Carswell agree with those of the late Dr. Armstrong.

Melanosis is a more common disease in horses, than the human subject; but it is principally met with in those of a white or grey colour; a fact, corroborating the doctrine of its origin from constitutional peculiarity. As Professor Carswell remarks, the circumstance is also favourable to the theory, which ascribes the origin of melanosis to the accumulation in the blood of carbon, which is naturally employed to colour different parts of the body, as the hair, rete mucosum, and choroid coat of the eye.

From chemical analysis, it would seem, that the substance of melanosis consists of fibrin, a black colouring matter, a small quantity of albumen, chloruret of sodium, oxide of iron, water, subphosphate of lime, and a few other salts in small proportions; and it is the general opinion, that the melanotic matter is essentially composed of the constituent elements of the blood. The colouring matter seems also to be a highly carbonised principle.

We know of no remedy for melanosis. Its causes are as obscure as those of fungus hæmatodes, the disease perhaps most analogous to it. The only chance of benefit depends upon the early removal of the disease by operation, when the situation of the part affected will admit of it. An eye affected with melanosis has been extirpated, without any relapse having followed the operation at the end of two or three years. Melanotic tumours, formed under the tails of horses, have often been cut away with permanent success. These facts prove that melanosis is not always quite out of the reach of the efficacy of surgery.

Scrofula, or *struma*, commonly called the *king's evil*, from the superstitious notion formerly entertained, that it was curable by the royal touch, frequently presents itself in the

form of glandular enlargements under the skin, swellings, whose progress is in general remarkably indolent, which soften very slowly, and at length frequently suppurate and burst, after which they remain a greater or lesser time as ulcers, and, after healing (which they do very tediously), often leave behind them callous irregular scars, incapable of obliteration.

Sometimes the disease occurs in the substance of the cutaneous texture, which it disfigures and alters in a most disgusting manner; and very often it attacks the ears, the eyes, the eyelids, the nostrils, and the lips, which it thickens and deforms in an extraordinary degree. In other examples, you will find it fixing upon organs more deeply situated, as the bones and joints, obstructing the organs for the conveyance of the lymph and chyle, or giving rise in the lungs, the peritoneum, and other parts, to those tubercular diseases, which in this climate, at least, are the greatest cause of mortality.

After what I have said, it is scarcely necessary for me to observe, that scrofula will not admit of a short satisfactory definition; and this, notwithstanding our familiar acquaintance with its usual seats, and its ordinary ravages and course. I may tell you, however, that it is characterised by a remarkable propensity to chronic inflammation of the lymphatic and mesenteric glands. The absorbent glands of the neck, and those under the jaws, are more frequently attacked by scrofula, than those of any other region in the body; and perhaps their being more exposed to vicissitudes of temperature, and to the irritation of porrigo, which is so common in children, may afford some explanation of this fact. Next, perhaps, the mesenteric glands are most frequently disorganised by it; and it is not unusual to find it affecting the glands in the groin, and even those in the axilla, and other situations. Indeed, I may say, that all the absorbent glands, in every part of the body, are liable to scrofulous disease.

Next, gentlemen, I may observe to you that scrofula always produces in the system a tendency to the formation of chronic abscesses, not merely in and about the absorbent glands, but in the general cellular tissue of the whole body.

As already mentioned, it likewise creates a disposition to the origin of tubercles in the lungs, liver, brain, spleen, and other internal organs. These tubercles are small, roundish, opaque masses, of a whitish, greyish, or yellow colour: when situated in the lungs, they sometimes gradually augment in size, until they are half an inch or more in diameter. More commonly, however, when they have become as large as a pea, they begin to soften in the centre, and thus communicate by one or more minute apertures with the neighbouring bronchiæ, or, remaining for a longer time closed, they are converted into collections of curdy half formed pus, termed *comica*, which, sometimes uniting together, form large abscesses, and these, bursting into the bronchiæ,

often leave considerable cavities called *tubercular excavations*. The most frequent seats of scrofulous tubercles in adults, are, first, the lungs, and then the small intestines; but, in children, their most frequent situations are in the bronchial glands, the mesenteric glands, the spleen, the kidneys, and the intestines, in the order I have enumerated.

If you regard tubercular phthisis with me as a scrofulous disease, it will make a material difference in the comparative estimate of the frequency of scrofula in children and grown up persons.

Scrofula is accompanied by a tendency to certain morbid changes in the spongy and cancellous texture of the bones, and also in the synovial membranes.

In the common language of surgery, gentlemen, we frequently say, that a person is scrofulous, though he may not have any visible disease about him, but merely certain appearances, usually regarded as emblems of a scrofulous constitution, or of a predisposition to scrofula. Thus, a fair complexion, light coloured hair, a fine thin delicate skin, exhibiting the minute ramifications of vessels, full-sized rather dilated pupils, and a remarkable whiteness of the albuginea of the eye, a tenderness of the edges of the eye-lids, a swelling of the upper lip, with some thickening of the alæ and tip of the nose, are known to denote a scrofulous constitution. In many instances the ends of the fingers are broad and clubbed, as the expression is, and the belly protuberant. Perhaps the doctrine of a fair complexion and light hair, being indications of a predisposition to scrofula, may have been carried too far, and certainly I should have been inclined to suspect, that it had arisen merely from the accidental circumstance of the greater number of children in this country being fair, and having light-coloured hair, had I not found it noticed by Alibert and other French pathologists, that scrofula is most frequently seen in France in the same description of children, where we know that dark complexions and dark eyes predominate.

You are not, however, to suppose, that a dark complexion is an absolute protection; for many scrofulous persons have dark skin and hair; and every surgeon of experience knows, how subject the African negro and other individuals of the dark races are to scrofula, when brought to this damp, cold, and variable climate.

It is frequently difficult, perhaps sometimes impossible, to draw with precision the line between scrofulous and some other diseases, because there is an insensible transition, or gradation, from one to the others. Yet certain forms of diseases present themselves daily, in which you can have no hesitation in pronouncing them to be scrofulous. Such are particular indolent swellings and abscesses of the lymphatic glands of the neck, certain diseases of the joints and spinal column, and various tubercular affections. Children are more liable

to scrofula than grown-up persons, the period of life most exposed to its attack being from infancy to puberty. Nay, if tubercles are to be regarded as unequivocal effects of scrofula, as many of the best pathologists believe, the disease may commence in the foetus; and you may see in my friend, Mr. Langstaff's Museum, portions of lung taken from a foetal subject, and evidently containing completely formed tubercles in them.

As puberty approaches, the disposition to scrofula lessens, and those, who have suffered from it in their childhood, sometimes become free from it, and bid defiance to its further annoyance. Females are generally considered to be rather more subject to scrofula than males. The disease is well known to be neither infectious nor contagious, it is not communicable from one person to another by inoculation, nor through the atmosphere; and the idea, that scrofulous nurses may impart the disorder to children, is one that is at present universally renounced.

Scrofula may make its appearance in almost any texture of the body, and is not, as is sometimes conceived, peculiar to the lymphatic glands, though they are perhaps more susceptible of it, than any other parts. The glands of the neck and those of the mesentery undoubtedly come within this remark; and next to those organs, I may say, that the skin, the lungs, the eyes, the ears, and the spongy parts of the bones are most frequently the seats of scrofulous disease.

Scrofulous inflammation is generally remarkable for the slowness and indolence of its character. Its attack is always more insidious, and its progress much slower, than the invasion and advance of phlegmonous inflammation. The acute pain, the throbbing, the firm circumscribed swelling, the bright red colour, and the quickness of the changes which attend all simple healthy inflammations, may be said to be entirely absent from scrofulous inflammation, as it usually presents itself. Neither does scrofulous inflammation, when situated in a lymphatic gland, or any ordinary texture, commonly produce at first any febrile disturbance; yet, when scrofula makes progress, or attacks organs of great importance in the animal economy, or extends its ravages to the large joints, the degree of constitutional derangement and of hectic is often such as to form a state of considerable and urgent danger.

Scrofulous inflammation near the surface of the body often begins with a soft swelling of the part affected, which is frequently one of the lymphatic glands. The covering of the gland becomes slightly thickened, and the gland itself has a doughy feel. As the swelling increases, it becomes more elastic, or even communicates the sense of a fluctuation; and, in this stage, you will generally notice a degree of induration under and around the tumour, with a more or less red or livid discoloration of the skin. If a puncture be now

made in the swelling, a thin fluid, mixed with flakes of a curdy substance, composed of fibrin, will be discharged, but only in trivial quantity, and rarely in the shape of good pus. The edges of the puncture next inflame, and the opening becoming larger, in consequence of the ulcerative progress, a dark yellow or brown sloughy-looking substance may be seen within it; and betwixt this substance and the skin a probe may be passed freely all round the sore. Indeed, it may be said to be one of the characters of scrofulous abscesses, when formed near the surface of the body, always to detach the skin extensively from the subjacent parts. If the disease be allowed to take its own course, without being punctured, a part of the skin becomes very thin, and of a light purple-red colour, afterwards bursting and discharging a thin fluid like whey, with which flakes of fibrin, and occasionally pus, are also blended. The redness continues, the surrounding hardness remains, the ulcerative process advances, and the case is now converted into an open *scrofulous ulcer* or *sore*, which is generally not disposed to heal up in a favourable and expeditious way. The cavity and sides of many deep ulcers and abscesses, resulting from scrofula, are noticed by Mr. Wardrop to be covered with a tough, yellow, fibrinous incrustation, that produces an impediment to the formation of granulations; and he accounts for the usefulness of laying open scrofulous abscesses, partly on the principle of its promoting the separation of this extraneous incrustation within them. In Dr. Baillie's *Morbid Anatomy*, the substance, which I am speaking of, is particularly mentioned, as presenting itself in scrofulous abscesses.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE.

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE VIII.

Diseases of the Small Intestines.

GENTLEMEN,—At my last lecture I was engaged in the consideration of disease of the small intestine: let us now resume the subject. You remember I mentioned to you that most of our knowledge of the inflammatory affections of the small intestine refers to the ileum, and that, in point of fact, we know little or nothing of disease of the jejunum. This, however, is not of much importance, as, of all the parts of the digestive tube, the jejunum is the least liable to disease, and is seldom or never engaged without the co-existence of disease in the ileum or duodenum. You recollect I drew your attention strongly to the extreme frequency of inflammation in the

lower third of the ileum, and the importance which it derives from this as well as from its insidious latency. I showed that it was one of the most common secondary lesions in typhus fever, and a frequent cause of death. This cannot be impressed too much upon your minds,—it is a point of pathology on which the best informed medical men are agreed. It may also, and very often does, occur as a pure idiopathic affection, without being preceded or superinduced by that morbid state of the whole economy to which we give the name of fever. I said it was extremely common in children; that here it was in many instances mistaken for worms, or bilious, or remittent fever; that it constantly occurred during the progress of *tabes mesenterica*, and often appeared to have the initiative. I alluded to the discussion which has arisen as to the question whether disease begins in the glands or mucous membrane, and stated that such discussions are useless, as it is impossible to separate the two affections in diagnosis or treatment, and practical medicine gains nothing by the distinction.

With respect to the symptoms of ileitis, I observed that they were those of a general affection of the digestive tube, the phenomena which indicate irritation at its upper and lower part being absent. That if you abstract from symptoms of a general affection of the intestinal canal, the vomiting and desire for cold drinks which characterise inflammation of the upper part, and the diarrhoea and tenesmus which denote disease of the lower part, you will have the diagnostic marks of an ileitis. At our last meeting I showed you some preparations illustrative of this disease; I intended to have exhibited others of the same kind to day, but regret I cannot lay my hands on them at present. Allow me to rehearse the symptoms of ileitis once more. Thirst, without desire for cold drinks; absence of vomiting, and of the characteristic symptoms of inflammation of the colon and rectum; early tympanitis, generally on the second day of the disease; absence of pain, but existence of tenderness on pressure between the umbilicus and the crest of the ileum; pointed tongue, of a dirty white on the upper surface, and red at the sides and tip; contracted features; quick, small pulse; fever, and, what I forgot to mention in my last lecture, scanty high-coloured urine, a very constant symptom, so much so, that I have known this disease mistaken for an affection of the kidney, and the patient treated accordingly. I must add, that the patient died, that the kidney was found perfectly healthy, the ileum in a state of violent inflammation, and the suppression of urine to be referred to this cause alone.

I drew your attention at my last lecture to the increased pulsation of the abdominal aorta and its immediate branches, and stated that I looked upon this as a direct sign of abdominal inflammation. I do not mean to say that every case of increased action of the great

abdominal arteries is significant of ileitis or intestinal inflammation. We see unusual pulsation of the abdominal aorta in hysterical females, and see it subside under the use of antispasmodics; we see it in painter's colic; we see it in cases of extreme emaciation; we see it in disease of the aorta, or of some of its first large branches. What I wish to draw your attention to is this: where we have this symptom in addition to other signs of inflammation of the digestive tube, it is of considerable value as a diagnostic.

You may remember I stated that ileitis, from being generally attended by fever of the continued type, has been frequently supposed to be simple continued fever, and that this was one of the consequences which resulted from the latency of the disease. Petit was the first who described this disease rightly. He described it under the name of entero-mesenteric fever, that is to say, fever depending on disease of the mesenteric glands and small intestine. The following is an outline of his description: "The attack comes on with debility, irregular fever, quick, small pulse, sunken countenance, perhaps some diarrhoea, a lustrous expression of the eye." I may remark here that the occurrence of diarrhoea without any evident affection of the great intestine, and *accompanied by fever*, is almost always a sign of ileitis. It too often happens that practitioners, as I before remarked, prescribe for names. In cases of pulmonary disease, if the patient has fever with copious expectoration, they say he is labouring under an attack of bronchitis; but in case of intestinal inflammation, accompanied by increased secretion, it is different; they merely say he has diarrhoea, and prescribe for it without connecting it with its proper cause. The general rule is, *that when you have diarrhoea with fever, there is inflammation of the digestive tube.*

In inflammation of the ileum the patient generally lies on his back, and avoids motion as much as he possibly can, his skin is dry and harsh; he is feverish; he has thirst, but little desire for cold drinks; he scarcely ever vomits; his alvine dejections are sometimes thin and purgative, sometimes figured and natural. But there is one circumstance which is of considerable importance in pointing out the amount of disease, even in cases where patients have considerable diarrhoea, and this is, that the diarrhoea is not sufficient to account for the extraordinary prostration. There must be some cause for the great reduction of vital power besides the mere diarrhoea, and I must state to you that there are few diseases which bring on such rapid prostration as inflammation of this portion of the digestive tube. In the advanced stage of this disease, the patients have cold skin, subsultus tendinum, petechiæ, involuntary discharge of urine and feces, low delirium, coma, gangrenous ulcerations of the back, sinking of the powers of life, effusions into the head and chest, in fact all the symptoms

which characterise the last stage of typhus. Generally speaking, the disease is more or less prolonged, and the patients die of exhaustion, but in some cases the approach of death is more sudden and formidable. Some of the ulcers pass deeply into the substance of the intestine, perforate all its coats in succession, the contents of the intestine escape into the peritoneum, and the patient is carried off by a rapid peritonitis.

Inflammation of the ileum is very frequently met with in children, and it is most important that you should be aware of the extreme frequency, as well as the symptoms of this disease, in those little creatures. There is one fact in pathology, which seems not to be generally acted on, that there is a class of diseases which are intra-uterine, and with which a child may be born. There are a great many cases of this kind on record, but still, I must confess, there is a great scope for investigation, and that our knowledge on this subject is imperfect. I believe that any one who has the opportunity of dissecting a great number of still-born children, or of those who die immediately after birth, would, by examining the state of the different cavities, and publishing the results of his examinations, earn for himself very great reputation. It is a well known fact that children may be born with hydrocephalus, with tubercles in the lungs, with acute inflammation of the stomach; nay more, children have been known to be born with chronic gastritis, and with old ulcerations in the ileum and colon. When children happen to be born with gastro-enteric disease, they are puny and weak; the fact of this occurrence is generally overlooked, the case is considered to be one of general debility, and hence most of those children are lost in consequence of their medical attendants being ignorant of the real nature of the disease. It is a very curious fact, too, that where enteric disease occurs in very young children, it is frequently met with without any accompanying fever, and this is a point of great importance. Here is a fact not generally known. A new-born infant has vomiting, swelled belly, contracted features, but at the same time he has cold skin and feeble pulse; he has no distinct symptoms of fever, and a puny and feeble state of constitution appears to be the prominent symptom. He dies, and, on opening the body, you find distinct traces of enteric inflammation. The younger the child is, the less will be the chance of fever occurring as a sign of enteric inflammation. It seldom happens that this takes place after dentition, but before it is very common.

Now, what are the circumstances which would enable us to recognise this disease in children who have passed the period of first dentition? If you find the child vomiting, thirsty, with swelled belly, hot skin, a tendency to diarrhoea, and an erythematous redness about the anus, you may be sure that there is disease of the digestive system; if the

child is restless, and you perceive that the symptoms of irritation of the head are coming on, you will be more certain, and in such cases pathology will inform you that the disease is chiefly in the ileum. In the advanced stage the diarrhoea is lessened, but the belly continues tympanitic, the child exhibits traces of long suffering, and the circumstance of the teeth not being developed gives it the appearance of premature old age, which cannot be mistaken by an experienced eye, and is a sign of long continued and extensive intestinal disease. In some cases, the child gets a common attack of diarrhoea; this is neglected, but after going on for two or three days, symptoms of fever begin to appear. Here we arrive at a practical rule. Where a child has diarrhoea, and after labouring under this for a few days, gets an attack of fever, you may be almost sure that it is a case of enteritis, and that you will be acting wisely in treating it as such. In the opinion of many well informed practitioners, that form of fever, which has been called infantile remittent, is only an example of this disease. In proof of this fact, Dr. Marsh, my friend and predecessor in this school, in his paper on jaundice makes some excellent remarks on this subject. "There is yet one form of disease of very frequent occurrence, the seat of which is in the stomach and small intestines. That to which I allude, is the *infantile remittent fever*, or, as it is vulgarly termed, the *worm fever* of children. Its characteristic symptoms, if closely analysed, will be found all of them to point to the mucous surface as the original seat of morbid action."—*Dublin Hospital Reports*, vol. iii.

It would be well for medicine, if the valuable information conveyed in Dr. Marsh's paper was more universally diffused. I feel convinced that many children fall victims to mal-practice under circumstances of this kind. A child gets symptoms of diarrhoea, has irregular or bad appetite, and swelled belly, the disease is called worm fever; he gets a dose of calomel and jalap, and perhaps passes some worms; for when we come to speak of worms, we shall find that disease of the mucous surface is intimately connected with worms, and, in the opinion of one practitioner, worms may be the result of enteric inflammation. Well, some worms are passed; the purgative is again used; the child may not pass any more, or he may pass one or two in the week to encourage the practice. But all the symptoms of intestinal inflammation, the diarrhoea, the tympanitis, the thirst, the fever, are supposed to depend upon the presence of more worms, and these are to be evacuated by purgative medicine, and thus the affair goes on, until the child falls into *tabes mesenterica*, or gets sympathetic inflammation of the brain, and dies of hydrocephalus. I regret to add, that in many cases of this kind the head alone is opened; a little fluid is discovered in the ventricles of the brain, the doctor's diagnosis of

the head is found to be correct, and all parties are satisfied. In cases of this kind, the early application of leeches to the belly, the regulation of diet, keeping the bowels gently open by enemata and mild counter-irritation, would have saved the patient. This is not mere theory, it is but a statement of facts, supported by the experience of practical men.

I wish to say a few words here with respect to *tabes mesenterica*. In a course of lectures like the present, it would be impossible to examine in detail the different forms of this disease; it will be as much as I can do to draw your attention to the general principles of its pathology and treatment. The term, *tabes mesenterica*, is employed to designate that species of consumption which depends upon disease of the mesenteric glands. The common idea formerly entertained with respect to this affection, and, I believe, still to a great extent, is, that the disease first commenced in the mucous glands, and from these extended to the lymphatic ganglia of the mesentery, which in their turn became enlarged, thickened, and less pervious, so that a sufficient share of nutriment cannot be absorbed, the consequence of which is, that the patient dies of atrophy and exhaustion. With such views of the case, the principles of treatment consisted in employing a class of medicines called deobstruent, the operation of which was supposed to be efficacious in removing this obstruction, this deposition in the substance of the mesenteric glands, and the enlargement by which it was accompanied. This was, and this, I am sorry to say, is the idea still entertained by many. What is the actual state of the science with respect to this disease? It is found that the glands are certainly changed in their structure, and that they are manifestly enlarged; but this is only a link in the chain of phenomena, for it has been proved, that in the majority of cases the disease is ushered in by enteritis, and that the swelling of the glands is the result of disease, propagated along the course of the lymphatics from the mucous surface of the intestines to the mesenteric ganglia. This preparation, which I shall send round, will give you an idea of the actual state of the disease. Here is one of the glands which has been cut through; it exhibits the cheesy texture commonly observed in this disease, but you can perceive there are a number of lines running towards each of the glands; these are the engorged lymphatics, which you see correspond with ulcers on the mucous surface of the small intestine. That this is the true pathology of the disease will appear from the following circumstances: First, it has been proved, that the glands of the mesentery commonly become inflamed, enlarge, and even suppurate, in cases of inflammation of the mucous membrane of the intestinal canal in the adult. A patient gets enteric inflammation and dies; on dissection we find distinct marks of disease in the intestines, and, in addition to this, we find that

glands evidently diseased. Here is one fact. In the next place, it has been proved that, in a great many cases of *tabes mesenterica*, if you retrace the history of the disease, if you go back to its first and earliest phenomena, you will find that it began with the symptoms of what has been termed remittent fever, or that the patient had enteritis or diarrhoea, which afterwards became chronic, and that then the symptoms of *tabes mesenterica* began to appear. In the third place, you will find that, in a vast number of cases, where a fatal termination has occurred, if you pursue your dissection, and slit up the whole of the ileum, you will discover numerous old ulcerations of the mucous membrane, and find that the lymphatics, which correspond with these ulcerations, are in a state of manifest disease. Lastly, it has been observed, that the best treatment for *tabes mesenterica*, is that which is calculated to remove enteric inflammation, and that the old treatment, founded on the principle of removing obstruction, by the use of alkalies, absorbents, and solvents, is erroneous and false in the majority of cases. So that we have proof of the origin of this disease in intestinal inflammation, drawn from the occurrence of analogous affections in the adult, from the phenomena of the disease in its early stage, from morbid anatomy, and from treatment. I think there can be no doubt that, in most instances, it commences by intestinal inflammation. Of course a predisposition to disease of the glandular system will favour the occurrence. But is there no case in which the disease has commenced in the glands, and where the mucous membrane of the digestive tube is secondarily engaged? My answer to this question is, in a few cases we cannot prove that the disease commenced in the mucous membrane, and there is no reason why the glands of the mesenterica should not be liable to primary tuberculous or scrofulous deposition as well as those of any other part of the body; but, in a vast number of instances, the enlargement of the mesenteric glands is secondary, and resembles the inflammation of the inguinal glands, which results from chancre on the penis. I would advise you to consult the *Commentaries on Pathological Propositions* by Broussais. On this subject, also, Dr. Mackintosh's *Practice of Physic*.

There is one thing more connected with this disease, which is of considerable importance, and to which I shall briefly draw your attention, and this is, that this inflammation of the glands of Peyer and Brunner, this *dothin-enteritis*, as it has been called, is a very common cause of slow convalescence in fever. You will meet with cases of fever, which will go on to the 17th or 21st day, and then something like a crisis takes place; you expect that from this time forward the patient will get progressively better; but, in the course of a few days, you will be surprised to find no amendment, and that he is not gaining strength; you feel his pulse, and find it quick and small,

his attendant informs you that he is restless at night, and when you ask him how he feels, he says he has no particular complaint, but that he is very weak, gets no sleep at night, and has no appetite. Under these circumstances you are anxious to find out what his disease is; you inquire into the state of the heart, lungs, and brain; you find no evidence of disease in any of these organs; you run over in your mind the symptoms present, the feverishness, quick pulse, want of appetite, restlessness, and finding some degree of abdominal tenderness and tympanitic swelling, you arrive at the conclusion, that the return of health and strength is impeded and delayed by the existence of a *dothin-enteritis*. The first person who discovered this fact was Dr. Cheyne. "In these cases," says he, "the distress of the patient often bore no proportion to the danger he was in; the former was very little, while the latter was extreme. The disease would proceed without violent symptoms; nay, a patient would seem to be recovering, although without any critical discharge; he would call for full or middle diet, and for days take his food regularly. The only circumstance in his situation which demanded attention was, that he regained neither flesh nor strength, and he expressed no desire to leave his bed. Then, his pulse again became quick and his tongue dry; and he would complain of dull pain and uneasiness in his belly, attended with soreness on pressure, and a degree of fulness in the upper part of the abdomen. Then came on a loose state of the bowels, and great weakness. Probably at the next visit the patient was lying on his back, with a pale sunken countenance, and a very quick pulse; his mind without energy. Then his stools (mucous) passed from him in bed, and the urine also. Perhaps a hiccup came on; next his breathing became frequent, in which case death was at no great distance."—In all these cases the mucous membrane and glands were found in a state of decided disease.

Now, what was the nature of this disease? It came on as a secondary affection during the course of fever, became more marked and intense, and finally destroyed the patient. I have seen very many cases of this disease. I give you this as a general rule:—when, after the apparent termination of a fever, your patient convalesces very slowly and imperfectly; when you find that he is becoming weak, that his pulse is quick, his belly tympanitic, his thirst still present, *and all this without evidence of disease in the respiratory, circulating, or nervous system*, you may suspect inflammation of the mucous glands of the digestive tube, which may terminate in deep ulcerations; and you will not be surprised if your patient should be carried off by rapid peritonitis, occasioned by an ulceration of all the coats of the intestine. I have witnessed many instances of the truth of this statement.

It has been objected to the doctrine, that

infantile remittent fever, and tabes mesenterica depend on inflammation of the mucous membrane of the digestive tube, because it has been found that purgatives are sometimes useful in the treatment of the disease; and those who bring forward this objection ask, "if purgatives give relief, how can it be intestinal inflammation?" Now, what are the real facts of the case? These cases, which have been relieved by purgatives, are cases in which purgative medicine has been given in the early stage, and has been productive of benefit; or, in other words, where the disease is only just commencing, and where its cause is proved to be the presence of irritating matter in the bowels. A physician is called to a case of this kind; he gives a purgative; a quantity of offending matter is evacuated, and the child gets better. You should act in the very same way, and have recourse to purgatives whenever you have reason to suspect the existence of irritating or indigestible matter in the bowels. You are to employ purgatives on the same principle as every one employs emetics, in cases where corrosive poison has been swallowed; but no one is inclined to think that he will be able to cure the disease by the continued use of emetics. But, unfortunately, persons do not attend to the actual state of the digestive tube; they go on prescribing purgative after purgative, until the irritation, which was originally produced only by indigestible matter, becomes exacerbated, and terminates in ulceration of the intestinal mucous surface, accompanied by all the symptoms of tabes mesenterica.

The treatment of this affection is both simple and easy, particularly when the patient applies to you at an early period. In the case of children, one of the first things you have to determine is, whether you shall have recourse to the employment of purgatives or not. If you happen to be called in at an early period, or if the patient has taken no purgatives, and there is reason to suspect a loaded state of the bowels, you will be right in employing some mild laxative. You cannot commence your treatment better than by prescribing some mild opening medicine, particularly when you discover that the patient has been taking indigestible improper food. This plan I think both reasonable and useful. You will frequently meet with cases in which all the bad symptoms will disappear after the use of a few laxatives. Here is a point on which the followers of Broussais erred. They declared that the exhibition of a single laxative would be to endanger the patient's life; and that the only treatment which could be relied upon consisted in the use of leeches, low diet, and cold water. But I think there is as much reason in giving a laxative to remove indigestible matter from the bowels, in a case of this kind, as there would be in giving an emetic in a case of gastritis produced by the presence of indigestible matter or corrosive poison in the stomach. But if, after having evacuated the

bowels, the symptoms of intestinal irritation should continue, you are not to persist in the use of purgatives; change your hand and attack the symptoms of intestinal inflammation, which have now decidedly commenced.

We shall occupy ourselves, gentlemen, at the next lecture, in considering the treatment of this disease in the adult as well as children, and then go on to the disease of the large intestines.

CLINICAL LECTURES

DELIVERED

At the Meath Hospital, or County of Dublin Infirmary, Session 1833-34.

BY PHILIP CRAMPTON, M.D., F.R.S.,
Senior Surgeon to the Meath Hospital, Surgeon-General to the Forces in Ireland, &c., &c.

LECTURE V.

Fractures and Dislocations.

GENTLEMEN,—I beg to direct your attention for one moment to this preparation; I alluded to it in a former lecture, but was not able to lay my hands upon it until this morning. It furnishes a very good illustration of the mode in which union takes place in an oblique fracture of the tibia and fibula, where due attention is not paid to the coaptation, as it is termed, of the fractured pieces. It also illustrates a kind of fracture of frequent occurrence, but which is, I believe, often overlooked; and it is in all probability owing to such an oversight, that the deformity in this case is to be attributed. The fracture, which passes obliquely through the tibia at its lower extremity, is accompanied by a fracture which passes through the fibula within an inch of its upper extremity. It is easy to perceive how such a fracture may take place. If the lower extremity of the tibia and fibula be fixed, as when the foot passes through a hole in the floor, or is caught in a narrow drain, while the whole body falls outwards; and if there be any hard substance interposed between the fibula and the ground which supports the bone for a great part of its length, that part of the bone which is deprived of its support will give way at its weakest point, and that point is immediately below its head, for here it is slender and not covered by the extensors and abductors of the foot. Now if the surgeon, finding that the fibula is unbroken at the point corresponding with the fracture of the tibia, concludes that it has not been fractured at all, and least of all at its upper extremity, he will make a very serious mistake, and one which will materially affect the comfort of his patient and his own reputation. Having heard and observed that when the fibula is unbroken no shortening of the tibia can take place during its consolidation, he pays but little attention to the coaptation; and, when

he comes to examine the limb at the end of three or four weeks, he finds, to his infinite mortification, that the leg is, as in this preparation, two inches shorter than the unbroken one.

Here is another preparation exemplifying union by permanent callus, which has been completed; and you perceive accordingly that all the occasional callus has been removed. This preparation illustrates fracture of the neck of the thigh-bone, external to the capsular ligament; and you can see that the neck of the bone is driven into the cancellated structure of the shaft close to the greater trochanter.

I shall for the present close the subject of fractures by reporting progress on the cases to which I made reference on Monday; and first, with respect to the case of a woman in the accident ward with fracture of the fibula. The fracture in this case, which was situated one inch above the lower extremity of the fibula, and unaccompanied with any other complication but a partial dislocation of the foot, was produced by a violent twisting of the foot inwards. In such cases, you will recollect, the fracture is chiefly caused by the violent traction of the external lateral ligaments which pass from the extremity of the fibula to the os calcis. When the foot is turned inwards, these strong inelastic ligaments act in a direction nearly at right angles with the axis of the fibula; the ligaments or the bone then must yield, and the latter I believe invariably gives way, the action of the ligaments being aided considerably by the sharp edge of the astragalus, which, pressed from within outwards by the tibia, acts as a fulcrum against the fibula. The fibula is thus snapped across just about the point where its extremity joins its shaft; and when the patient attempts to bear on the limb, the astragalus turns outwards for want of its accustomed support, and away goes the foot. In our case the woman did not lay her weight upon the foot after the accident, and accordingly there was little or no displacement. The foot was placed in Dupuytren's apparatus for the space of twenty-five days; a figure of eight roller was then applied firmly round the ankle-joint instead of the splint and cushion; with this the limb was kept secure until consolidation was firmly established, and this day the woman is discharged cured. It will be at least two months before she will be able to walk without lameness, in consequence of the length of time which ligamentous parts take in recovering their proper flexibility. The recovery of the strength of the joint after fracture of the fibula is considerably promoted by the salt-water douche and friction with some animal oil. Fresh goose-grease, the favourite remedy with the poor of this country, seems to answer the purpose very well.

With respect to the case of compound fracture of the tibia, I have only to say that it is going on as favourably as possible; no new

abscesses have formed, and the discharge is diminishing daily, but there is not as yet any thing like consolidation. This process will not commence, or rather it will not proceed further than granulation, until all communication with the external air is cut off by the closing of the wound.

The compound fracture of the olecranon in the Male Accident Ward is still in a hazardous state. The patient's general health, however, holds up pretty well under the profuse discharge and irritation necessarily attendant on an open joint. You have seen that abscesses still continue to form about the joint. On Saturday I was obliged to open a larger one, which communicated with the cavity of the joint, as was apparent from the escape of synovia along with the pus. On that occasion I pointed out to you the peculiar characters which denoted this communication. Whenever you see an abscess in the neighbourhood of a joint, and find, on opening it, that a clear and nearly colourless fluid, like white of egg, escapes along with the pus, you may be sure that it is synovia, and that there is a communication between the abscess and the cavity of the joint. In cases like this a great deal of time must elapse before a cure can be accomplished, in consequence of the slow ulceration of the cartilages, and the subsequent formation of granulations on the ends of the exposed bones, by which the process of consolidation is to be established. Besides, the only mode in which an injury like this can be repaired is by ankylosis, a much more complicated process than that by which compound fractures, under ordinary circumstances, are united. The treatment here consisted in supporting the patient's strength by nutritious, but not stimulating food; we have put him on full diet, with a quart of bottled porter daily. As he has no perspirations, hectic fever, or diarrhoea, he does not require bark, mineral acid, or opium. The parts are kept steady by splints, the wounds are dressed with the Peruvian balsam, and the fore-arm is bent at nearly a right angle with the arm, in order that when ankylosis takes place, the limb may be in that form in which it is most usually employed; and in which it proves most serviceable. Under this treatment the man is going on as well as can be expected; to-day he is in a more favourable state than he has been since he entered the hospital. From lying long in bed he has got sloughing bed sores along the spine and on the sacrum. I have ordered him, therefore, to be placed on one of Dr. Arnott's water beds, and you will have an opportunity of observing the favourable consequences which will ensue from this change.

From the consideration of fractures we naturally proceed to *dislocations*; and, as we had an opportunity of reducing a dislocation of the humerus on Monday last, I shall make a few observations on the subject. The humerus may be dislocated in three directions: first, *downwards*, in which the head of the bone is

lodged in the axilla, and rests on the cervix of the scapula. Secondly, *forwards*, or, as the French surgeons term it, *inwards*, in which the head of the bone is lodged immediately below the clavicle and under the pectoral muscle; thirdly, *backwards*, in which the head of the bone is lodged on the dorsum of the scapula, beneath its spine, a little below the acromion process, as you see here. (*Dr. Crompton here exhibited some highly finished drawings illustrating the position of the head of the humerus in the different forms of dislocation.*) Upwards, it cannot be dislocated, as you perceive, without fracture of the acromion and coracoid processes.

I have had the good fortune to meet with two instances of dislocation, which I was enabled to examine accurately by dissection a few hours after the injury had been received: these were the dislocation downwards and the dislocation forwards. You will find, in the 7th and 8th numbers of the *Dublin Medical Journal*, a full account of these cases, with some remarks on the pathology of dislocation of the shoulder joint. (*Mr. Crompton here exhibited a drawing of the parts.*) Here is the dislocation downwards into the axilla. The man from whom this drawing was taken had his shoulder dislocated, and was killed nearly at the same moment by a wall falling on him while engaged in digging under the foundation of a house. On examining the body, eighteen hours after death, it was found that, in addition to an injury of the head which had proved fatal, the right humerus was dislocated into the axilla. Of this I made a careful dissection previously to reducing the dislocation, and was so fortunate as to obtain a drawing of the parts by an eminent artist. Here is the drawing (*showing it*), and it is an accurate representation of the state of the parts in a recent dislocation downwards. This and the other case of dislocation forwards are, I believe, with the exception of Sir Astley Cooper's case of dislocation downwards, the only cases on record which illustrate the actual state of the parts in a recent dislocation. Here is the capsular ligament, represented by this irregular margin, torn from the lower part of the neck of the humerus to the extent of more than half its circumference, the torn edge appearing like a crest over the head of the bone. You see the rent in it is so considerable that it would admit of the passage of a body much larger than the humerus, and consequently that it could offer no sort of resistance to the return of the head of the bone. The head of the bone, which you see has pushed the *teres minor* downwards, rests on the inferior costa of the scapula, or rather on its neck. Here is another lesion worthy of your attention; you perceive the injury which has been done to the articular muscles as they are called; the *supra*, and *infra spinatus*, and *teres minor*, are torn from the greater tubercle of the humerus, to which they were attached, and they have carried with them a portion of the tubercle

itself. Here is another plate, it is an exceedingly good view of the dislocation forwards. The original preparation from which it was taken may be seen in the museum at Park-street. Here is the head of the bone lodged on the neck of the scapula, at the root of the coracoid process, but extending as far as the notch in the superior costa. It passed through a rent in the capsular ligament, above the tendon of the *subscapularis*, detaching this muscle from its connection with the inner face of the scapula, and pushing its fibres downwards. The *supra* and *infra spinatus* are very much on the stretch, but their fibres have received no injury. Now, remember this, in the dislocation downwards, the head of the bone passes under the lower edge of the *subscapularis*, or bursts through a portion of its fibres near to its lower margin, pushing the bulk of the muscle upwards, and detaching it to some extent from the inner surface of the scapula. When the dislocation takes place forwards, the head of the bone passes over the upper edge of the *subscapularis*, pushing its fibres downwards.

I have not had an opportunity of examining after death any case of the dislocation backwards, on the dorsum of the scapula, and I believe that it is very seldom seen under any circumstances. During the course of my professional life, I have met with only one instance; Sir A. Cooper, who has had vast experience in dislocations, has met but two, and Baron Dupuytren only one. The case which I witnessed occurred a good many years ago in the person of a gentleman named Gresson, from the county of Meath. This dislocation was reduced, not indeed by regular practitioners, but by the Messrs. Taylors, the celebrated bone setters, near Manchester. Mr. Richards, Mr. Colles, and myself attempted to reduce it by pulleys, but the dislocation was of two months' standing, and we were unsuccessful in the first effort; the gentleman got alarmed and dissatisfied, and, at the suggestion of a friend, went over to the Taylors, who got five men to pull away at the limb until the bone returned to its proper place. The length of time it was out must have added considerably to the difficulty of reduction, and this brings me to speak of another important point in the treatment of dislocations of the shoulder and other joints.

The great obstacle to the reduction of a recent dislocation is now, I believe, universally admitted to be muscular contraction, caused by the irritation excited in the muscles by their being thrown into constrained positions, an irritation which is further increased by the violence which they suffer during the process of reduction. In cases of old dislocation, there is a new difficulty superadded to this; here we not only have the resistance which depends on muscular contraction to deal with (for the muscles have now accommodated themselves to their new positions, and are almost incapable of being stretched), but we have also an obstacle to contend with, arising from the for-

mation of strong membranous adhesions. A new capsule of condensed cellular tissue has been organised, holding the head of the bone firmly in its situation, and presenting a very serious, and, after a certain period, an invincible obstacle to reduction. Even in so short a time as eighteen days, it appears a new capsule may be formed, as you will find in a case mentioned in Mr. H. Thompson's paper in the *Medical Observations and Enquiries*. In Mr. Thompson's case you will find not only that a new capsule was formed, but that the parts were so firmly bound together, that no force short of what would break the bone, would be sufficient to remove it from its position. In a case lately recorded by Sir A. Cooper, you will find that, even after death, the principal cause of resistance was found to depend upon the muscles, and that he was unable by his own strength (which is none of the least) to reduce the dislocation even in the dead subject. He was determined to know the reason of this, and divided the muscles one after another, cutting through the coraco-brachialis, teres major and minor; he next divided the deltoid muscle, and found that the supra spinatus, which was put on the stretch, was the great opponent to reduction.

Now I wish to make you understand this. In Mr. Thompson's case, as well as mine, the articular muscles were torn from their attachment to the lesser tubercle of the humerus. But in Sir A. Cooper's case these muscles had preserved their attachment to the tubercle unbroken, and he ascertained, as I have just stated, that the great difficulty, which he encountered in reducing the dislocation, arose from the tense state of the supra spinatus, which, in going to be inserted into the greater tubercle, passes over the upper surface of the head of the bone. Now here is a dry preparation of the shoulder joint; imagine this riband to be the supra spinatus, here is the tendon of it coming out from under the acromion to be inserted into this tubercle. One of the uses of this muscle, you know, is to assist in elevating the humerus, and to raise the capsular ligament, so as to prevent it from being nipped between the head of the humerus and the edge of the glenoid cavity when the arm is raised; its action also powerfully tends to prevent dislocation downwards into the axilla; here is the supra spinatus, stretched across, and dragging against the face of the glenoid cavity. Here is the lower lip of the glenoid cavity, over which the supra spinatus passes, and on which it acts as a fulcrum. The more tightly this muscle is drawn, the more firmly will the head of the humerus be pressed against the neck of the scapula, and the greater, consequently, will be the difficulty of reduction. The longer it remains unreduced, the more is the head of the bone drawn by the conjoint action of the subscapularis, teres major, pectoralis, and latissimus dorsi, under the ridge of the scapula. But if, while making extension, you press the head of the bone

downwards, it will clear the brim of the glenoid cavity, and start into the socket by the mere traction of the muscles.

As the obstacle to the reduction of a recent dislocation is proved to depend on the contraction of the irritated and extended muscles, and not on any condition of the capsular ligament, the point to consider is, first, what muscles are chiefly concerned in keeping up this resistance, and, secondly, by what means you will elude their force. It would seem that the muscles which offer the greatest resistance are the articular muscles, when they retain their attachments to the head of the bone, together with the deltoid, pectoralis major, and latissimus dorsi. It is probable, however, that all the muscles proceeding from the scapula are more or less concerned.

One of the first principles, therefore, in the reduction of all dislocations, is to diminish this power of muscular contraction, as unless this is done, it is worse than useless to attempt to replace a dislocated bone by main force. There are many means of accomplishing this object. First, by bleeding, taking care to make a large opening in the vein, (not of the dislocated arm, of course,) and to keep the patient standing while the blood flows. The quantity of blood lost, the agitation produced by the novelty of his situation, and the pain that he suffers, make the patient so weak that he soon becomes faint, and in this state the force of muscular contraction almost entirely ceases, the power of resistance is completely overcome, and there is scarcely any effort necessary to accomplish reduction. The debility induced by bleeding may be increased to almost any extent by the administration of tartar emetic. One-eighth of a grain, given every half hour, will soon cause so much nausea, as to bring down the muscular strength of the most powerful man to the level of the weakest. The warm-bath is recommended with the same view, but it occupies a good deal of time; it cannot always be conveniently procured, and the patient is liable to catch cold after it, when exposed to the air (half naked) during the process of reduction.

This principle is chiefly applicable to cases where the bone has been out of its place for several hours or for some days. But if you happen to be on the spot immediately after an accident of this kind has occurred, it is seldom necessary to lose time in doing this; the patient has received a severe shock, the power of life, and consequently of muscular contraction, are reduced, and there is in general very little difficulty in effecting reduction. In the case of the man whose dislocation was reduced here on last Monday, venesection was performed because the patient was very muscular; the bone had been out of its place for nearly sixty hours, and ineffectual efforts had been made elsewhere to reduce it.

When you are once aware that the chief difficulty you experience in reducing a humerus arises from the contraction of the infra

and supra spinatus muscles, you consider how you may best overcome this obstacle, and you examine in what direction traction will be most efficient in liberating the head of the bone. By drawing the humerus in this direction (downwards), you will be acting very correctly, so far as the *direction* of the extending force is concerned; and when the extending force is sufficient to bring it over the brim of the glenoid cavity, the force of the muscles themselves will draw it into its natural situation. This is what occurs when you effect reduction by the heel in the axilla, but as you are acting directly against the contracted muscles, there must be a great waste of power. Here is the supra spinatus; this must be drawn downwards, over the face of the glenoid cavity, and lengthened, before you can expect to free the head of the bone from the lower lip of the glenoid cavity. Now what is the best mode of liberating the head of the bone? Raise the arm gradually upwards (in this way), observe as it ascends the head of the bone gets off the neck of the scapula, and approaches the convex slippery surface of the edge of the glenoid cavity; it now glides over this, and slips with velocity into its situation. (*Mr. Crampton here illustrated this, by showing the passage of the head of the humerus in a dry preparation of the bones of the shoulder-joint.*) You may have observed, that, in the dislocation of the humerus downward, which was reduced here on Saturday, without any other force than my own strength, this mode was adopted with success. You will, therefore, in all recent cases of this dislocation, first try this plan before you have recourse to any other; place your patient sitting on the ground, make a surgeon's knot (in this way) with a towel or silk handkerchief, and put it round the patient's wrist. If you fasten it round the arm the pressure will stimulate the muscles and increase the resistance; then stand upon a chair and raise the patient's arm, drawing it upwards with all your force, as if you wished to lift him off the ground. You will not pull the arm upwards alone, but also incline it obliquely forwards towards the patient's face. The great advantage of this mode of reduction is, that you often can effect it without assistance, it requires but little force in comparison with the other modes, and you saw that I was able to reduce the dislocation on Saturday by a force not sufficient to raise the man from the ground.

But if you are not able to accomplish the reduction in this way, there remains a very effectual method of doing so by means of a ladder, the mode of employing which will be easily understood by a reference to the plate in the eighth number of the Dublin Medical Journal. The great objection to the use of the pulleys is, that you do not know the extent of the force you apply, nor can you conveniently change its direction; besides, when the pulley is drawn tightly there is an uniform degree of

tension, and there can be no motion employed to disengage the head of the bone, a very important thing in the reduction of old dislocations. When you employ the ladder, the patient is placed standing on the ground, with his legs through the rounds of the ladder, and a folded sheet, passed under the axilla, (to form the counter-extension) is held by two or three assistants, who stand upon a firm table; the foot of another assistant is placed on the lowest round of the ladder, to prevent its rising when the upper end is pressed down, while a third seizes the upper end of the ladder and slowly depresses it, until the surgeon, who stands astride of it, close to the patient, announces that the bone has returned to its socket. While the extension is in progress, the surgeon, from time to time, presses the upper part of the humerus downwards, to disengage it from the brim of the glenoid cavity. I do not know of any thing more useful than this, for, by pressing it downward, you liberate it from its confinement behind the edge of the glenoid cavity, and, once liberated, it snaps at once into the socket. Besides this, the surgeon, by standing astride of the ladder, has it in his power, by the pressure of his knee on either side, to give a lateral motion to the lever while extension is still in operation. You will, therefore, when you want to disengage the head of the bone, push it from you in this way, as if you wished to increase the dislocation, and thus homœopathically, as it were, accomplished your intended purpose.

There is another point connected with reduction, on which more stress is laid by the French surgeons than by us, and that is the taking the muscles by surprise. If you divert the patient's attention from the circumstances of reduction altogether, the muscles are as it were thrown off their guard, one of the principal impediments to reduction is in a great measure removed, and you obtain a most favourable opportunity for accomplishing your purpose. If you jump from a height of eight or ten feet, and are prepared for it, the muscles all act simultaneously, and you come down without any considerable shock, and with no injury. Yet if, in descending a stair-case, you miss but a single step, you may have the foot turned under you and get a fracture of the fibula, or perhaps break both bones of your leg. The ankle, or the leg, is as strong in one case as in the other, but the muscles are not prepared to direct the external force in the direction of the axis of the bone, it therefore pulls obliquely and the bone gives way. Now, when you attempt reduction without diverting the patient's attention from your proceedings, he unconsciously sets himself against you and opposes his force to yours; but if you can direct his attention completely from the reduction the case is quite otherwise. If you give a man, standing with his back to the fire, (as you no doubt have often done,) a slight blow with the side of your hand under the ham, the knee gives way, and you nearly throw him.

down; but, if he be aware of your intention, he remains firm, and no force that you can apply will make the limb give way. Get your patient, then, into conversation when you are about to attempt the reduction of a dislocation; ask how he got the accident, and you will often succeed in diverting his attention, for this is a theme on which the generality of patients are very communicative, and, while he is deeply engaged in recounting all the minutiae of his adventure, seize on the moment for proper extension, and you will often be able to employ it with decided effect. In the French hospitals it is very entertaining to hear the dialogue which takes place between the surgeon and the patient. I remember having seen Baron Dupuytren reduce a dislocation in a female, and it was most amusing to hear how ingeniously he irritated her by his abuse, and with what interest she repaid him. While she was pouring a torrent of abuse on him, and totally forgetful of the dislocation, M. Dupuytren gave her arm a sudden jerk over his own and reduced it at once.

The reduction of a recent dislocation forwards is in general easily effected. You have only to place your fore-arm under the axilla, and using the patient's arm as a lever, you press the elbow against the ribs, and the head of the bone is readily forced back into the glenoid cavity. Should this manœuvre fail, the gradual extension upwards, in the manner I have just described, will be sure to succeed. This however only applies to the recent or primary dislocation forwards. There is another form of this dislocation, which the French surgeons call *secondary*, in which they conceive that the head of the bone, which was first lodged in the axilla, is afterwards drawn by the contraction of the muscles under, or rather below the clavicle. There has been much controversy respecting primary and secondary dislocation forwards, but the case, which I have described this day, the preparation of which may be seen in the Museum at Park-street, sets the question at rest for ever.

There is, then, such a *primary* dislocation as dislocation forwards, but it is equally true, that the head of the bone, having escaped into the axilla, may be drawn upwards under the clavicle, constituting the *secondary* dislocation forwards of the French surgeons.

PROFESSORS LIZARS ON MEDICAL REFORM.

THE first point to be decided is, for whose benefit is reform required?—Is it for the community, or for the medical profession? All reforms, whether political, borough, or medical, are intended for the good of the community; and hence it is evident, that that reform is necessary, which will ensure to the

public relief from a state of disease in the most scientific, beneficial, and cheap manner.

The following is a simple and liberal reform, and does not interfere with the vested rights of the corporate bodies and medical institutions of the country, excepting *in futuro*, and only so far as regards their pecuniary emoluments, many, if not the whole, of which they have usurped the right to levy from time to time, and which are consequently gross impositions. Each of these institutions may still continue to enjoy their exclusive privileges in a modified degree, and be held in as high estimation as ever by the public, provided they exert themselves in a scientific manner, and not in the *levying of taxes*.

The Medical and Surgical Boards or Institutions have evinced considerable difficulties in deciding upon the amount of knowledge requisite to be possessed by aspirants to degrees and diplomas, as is evidenced by the yearly changes in their curriculums of study, and the tyrannical and absurd modes ordered to be pursued by the teachers to enforce attendance on their prelections. And it is doubtful whether some of these bodies have not been influenced by interested motives, in order either to fill their own coffers, or the pockets of their professors. This alone ought to disqualify such bodies from regulating the curriculum of study.

From all this it is evident that *examination* only can form the test of the fitness of the physician or surgeon, and the safeguard to the community; for any one with a retentive memory may prepare himself to answer the questions as at present constituted; and hence the encouragement given to grinding. And not a few instances might be adduced of young gentlemen, grossly ignorant in their profession, having passed the ordeal of examination.

Now that anatomy or dissection is legalised, such an examination can be pursued, as will enable the examiners to decide with greater certainty upon the abilities of the young men, who are to take upon themselves the important and responsible charge of the lives of their fellow-creatures. This hitherto could not be done.

The examination might therefore be as follows:—

1st. Let the candidate enter a room in which there is a dead body, a case of scalpels, and a written proposition to him, to display the minute anatomy of the nerves, blood-

vessels, and muscles of the face and neck on the one side, and the surgical anatomy on the other side. Let him be left alone, and when this task has been performed, let him ring the bell, and the umpires or examiners enter, and decide whether he has executed the dissection scientifically. Let him next demonstrate what he has dissected, and also some of the important viscera, as the anatomy of the heart and lungs, or stomach, or liver, or kidney, with their functions. Let him then perform some of the operations of surgery, as the securing the superficial femoral artery, the amputation of a finger, fore-arm, and leg, and also demonstrate the parts concerned in these operations.

In order to test his general knowledge of the English language, for I can see little utility to the public what his acquaintance may be with either the dead or the other living languages, let him write down some of the physiological theories, as respiration or digestion; and the same test of writing should be kept in view in his chemical, botanical, and other examinations. And his concluding examination might be a written thesis, as, for example, on the blood, or electricity, germination, fever, or aneurism.

2ndly. Let him enter into a chemical laboratory, tell the names of several of the substances, compound some, and analyse others; for example, let him name some of the alkalies, and earths or metals, and their compounds; make hydrogen, nitrous ether, and carbonic acid, analyse and test arsenic, the mineral waters, &c.

3rdly. Make him now go to a botanic garden, or to the fields, and tell the names of a few of the medicinal plants, and their properties and doses.

4thly. He should next enter a pharmaceutical laboratory, name several of the medicines, and combine and analyse a few, also mention their doses and uses, and write some prescriptions.

5thly. A pathological museum may then be consulted, and he be desired to describe some of the preparations, and be interrogated on the healthy and diseased actions and structures of the organs affected.

6thly. The medical wards of an hospital may now be entered, and he be requested to examine some of the patients, tell their diseases,

and prescribe for them; also the pathology, causes, prognosis, and treatment of them.

Let him do the same in the surgical wards.

The preceding examination ought to be conducted in public, by a quorum of examiners, about six in number, from the Colleges of Physicians and Surgeons, or from the general practitioners of the city, or town, all who at present possess a degree or diploma being eligible, and let one of the quorum of examiners be a teacher of that science, or branch of medicine which is under examination. If the general practitioners be considered the preferable, which is my own opinion, as there are many talented men of the army and navy, as also others, not belonging to the Colleges, and as this class of examiners would include the Colleges, the examiners might be appointed by the mayor, or provost, or chief magistrate of the town to which they belong, when a candidate signified his intention of submitting himself for their examination. The examiners, from whatever class they are chosen, ought to be elected by ballot, in order to secure impartiality, and give confidence to the candidate; and a new set of examiners should be elected monthly, to afford greater security and satisfaction to the candidates.

The fees for these examinations should be on the lowest possible scale consistent with the character and *status* of the profession, and the degree or diploma ought to be extended on unstamped parchment, as is the case with that of the College of Surgeons of Edinburgh. Government should set the example, by surrendering the paltry sum accruing annually from degrees of medicine. And the said degree or diploma, so meritoriously obtained, ought to qualify the candidate to practise or teach his profession in any part of his Majesty's dominions, and render him eligible for any situation in his profession, as that of physician or surgeon to any hospital or dispensary, and also be his passport for becoming a Fellow of any of the Colleges of Physicians, or Surgeons in England, Ireland, or Scotland.

If a parliamentary inquiry shall take place, and it shall be recommended that only one Faculty of Medicine and Surgery is necessary for each of the three kingdoms, each possessing equal privileges, then a quorum from such a body would do equally well. This Faculty would, in some measure, resemble that of the Fa-

culty of Physicians and Surgeons of Glasgow ; and the sooner all distinction between physicians and surgeons is done away with, the better, as it only creates discontent and jealousy. It does not appear to be necessary to condense the different Colleges, or Faculties of Physic and Surgery, into one in Scotland ; all that is essential for the good of the community is, that, whenever degrees or diplomas are granted, it is necessary that the means here pointed out for examination are attainable in the place where these are conferred ; for the more rivalry the better for the teachers, the students, and the public.

By adopting the foregoing plan, there would exist no monopoly, as at present enjoyed by the Universities and some of the Colleges ; and a young gentleman might study where and when he pleased ; but he would be compelled to acquire such really useful medical knowledge as would qualify him most efficiently for the awful and responsible duties of practice. And this knowledge by being attainable at any school, and under any teacher, would be purchasable at a much cheaper rate than at present.

In the appointment of Professorships to Universities or Colleges, I would suggest a somewhat similar mode of testing the qualifications of the candidates. Thus : if it were a Professorship of Anatomy that was vacant,—let the candidates be put alone into a dissecting room, and display a portion of the human body, and, at a certain hour, retire, when the umpires chosen by ballot should enter and decide (the public being also admitted) which is the best dissection. Next demonstrate, in turn, their dissections, and also other parts of the *subject*, as the eye or brain. They might then describe the functions of the eye, illustrating these with optical diagrams, drawn at the time by themselves ; and afterwards describe the organs and functions of respiration and circulation, with the different theories, from Harvey down to the present day.

A similar mode of testing the qualifications of a Professor of Chemistry, or any other science or branch of medicine, might be adopted.

Those who wish to practise as druggists, chemists, or apothecaries, might be examined only on chemistry, botany, and pharmacy, as pointed out in the second, third, and fourth clauses. But let any one who takes the degree

or diploma of general practitioner, pursue the calling of chemist, druggist, or apothecary, if he pleases.

With regard to quacks and other impostors, I do not think we should interfere or legislate further than this, that there might be published a list of qualified practitioners in every town, and corrected annually, so as to guard the public against quacks ; and it might be left to the public prosecutor, or to any private individual, in the event of his sustaining injury from the prescription or operation of an unlicensed practitioner, to sue for damages, and such penalties as the legislature might authorise. It ought also to be provided that no unlicensed person should be authorised to sue for, or recover, in any court in the kingdom, any sum for attendance or medicines supplied by him.

JOHN LIZARS,

Professor of Surgery to the
Royal College of Surgeons,
and Surgeon to the Royal Infirmary, Edinburgh.

Foreign Medicine.

Improved Shoe for Congenital Club Feet.

SIGNOR CHIESA has directed his efforts to improve upon the shoe, invented by Scarpa, and used by him in the treatment of this malady. The improved one serves either for the right or left foot, is capable of being employed in individuals of even 14 or 15 years of age, and also is available in distortions produced by rickets. That the shoe might be applied better, and embrace the foot more firmly, the form has been changed from a simple sandal to that of a common shoe, with a sole and upper part of leather, the latter being extremely pliant. The upper leather is supplied on its inside, at the part corresponding to the heel, with a pad, shaped like a reversed cone, which fixes the heel firmly in its place : the vertical steel spring remains, and can be moved from one side of the shoe to the other ; on each side there are small flaps to restrain the spring, which might push the foot in the opposite direction. Different kinds of pads can be adapted to the shoe, for the purpose of suiting every kind of deformity, and the spring may be lengthened when required.—*Gazette Médicale*,

New Instruments for performing the high Operation of Lithotomy.

M. Leroy d'Etiolle presented to the Academy of Medicine some improved instruments, with the intention of facilitating the operation of lithotomy performed above the pubis. The first of these instruments is a curved trocar, of which the point is flattened transversely, and which contains a hidden cutting blade on its concave surface. The second consists also of a curved trocar, furnished with a cutting blade, but the point of this is flattened laterally, and the canula is composed of two lateral halves, which can be separated by a peculiar mechanism. The third instrument resembles the forceps of Sir Astley Cooper, and is introduced closed into the bladder, as an ordinary sound, when there, the two branches, being expanded, raise and stretch the anterior walls. The fourth and last part of the apparatus is a double hook, which, being fastened, keeps the wound open by means of its two branches. M. Leroy d'Etiolle considers that the two great difficulties of avoiding the peritoneum and preventing the retraction or sinking down of the bladder, after the division of the latter, are overcome by the use of these instruments. He first divides the skin with an ordinary bistoury, and then pushes the first-mentioned trocar through the linea alba, about two inches above the symphysis, its concavity being towards the pubis. The aponeurosis being traversed, he withdraws the point, and directs the blunt end of the canula downwards towards the pubis, so as to avoid the peritoneum, then, by pressing on the instrument, the blade is made to open, and cuts the linea alba as low as the symphysis. Having proceeded thus far in the operation, and having opened the forceps introduced into the bladder, he plunges in his second trocar, the concavity being still directed downwards, and having separated the two halves of the canula, which hold the edges of the wound apart, enlarges the aperture to a convenient size, by means of the blade situated in the instrument. Then, having attached the hooks and withdrawn the trocar, he proceeds to extract the stone.

The Immoveable Apparatus used by M. Larrey in the treatment of Fractures.

M. Bérard has lately published some remarks upon this apparatus, which he has almost entirely

adopted for the treatment of fractures, and from which he has found the most signal benefit. Out of 24 cases of fractures, (principally of the leg), treated in this way, 18 have been cured without the least appearance of deformity; 3 terminated in a trifling deformity, or shortening, and three in death. One of the cases, which terminated in deformity, was a fracture of the leg, accompanied by swelling and gangrenous phlyctenæ, the apparatus was applied for 50 days, but without any signs of union. In another of these cases there was oblique fracture of the femur, and the patient was so very intractable, that it became necessary to abandon the use of this apparatus, and to apply permanent extension, by which means union of the bone, with a shortening of four or five lines, was procured. In all the fatal cases, death was occasioned by circumstances which the apparatus neither could have occasioned nor prevented.

Thickening of the Bones of the Cranium in an Infant of 18 months.

M. Breschet lately attended an infant, which had been affected from its birth with convulsions, occurring at short intervals. Some time before its death these convulsions became continued and very violent, and the child died when 18 months old. It was supposed that pressure upon some part of the brain would be found, but this did not prove to be the fact, the whole of the bones of the cranium however, except at the base, had acquired such a density, that in some places they were not less than an inch in thickness; the anterior fontanelle was not effaced, and the bones of the face did not participate in this increased growth. M. Breschet stated, that he had seen cases of this kind in old persons, and even in adults, but that this was the first instance of its occurring in so young an infant, which had fallen under his observation.

Preparation of the Hibiscus Esculentus.

A substance called Allahtaim du Harem à la Sultane Bahmia has been recently imported into France from the regions of the East. It is a powder similar in colour to café au lait, of a very savoury taste, and of an odour *sui generis*; the plant from which it is prepared is the hibiscus esculentus, or *Sultane Bahmia*, which the people of the East, and of many

countries of the New World, commonly use for food, and which the women in the Antilles esteem as very delicious. From numerous experiments made at the Hôpital St. Louis, M. Bielt considers this substance as particularly easy of digestion, especially in cases where there exists an extreme susceptibility following either gastro-enteritis or enteritis. M. Velpeau has made frequent use of it in persons disposed to pulmonary phthisis, to any of the irritations of the chest, to rheumatism, or to gastro-intestinal inflammations, &c. MM. Broussais, Baron Michel, and many other distinguished physicians agree entirely in the above opinion, and have had frequent opportunities of appreciating its utility during convalescence.

On the Influence of Weight upon the Circulation and upon Elevation of the diseased part, considered as a therapeutic agent.

From some experiments upon the effects of

weight upon the circulation, Professor Gerdy, of the Hôpital St. Louis, has been led to apply the law of weight even to combat some kinds of disease. He found that ulcers of the legs, raised upon an inclined plane, were rendered pallid, secreted less pus, and became covered with a scab, under which they rapidly healed. The arm of a patient, which was severely contused and considerably swollen, was elevated upon an inclined plane, and retained in that situation, when the swelling diminished, and the patient rapidly recovered. In another case of the same kind, where there was considerable ecchymosis, a diminution of an inch of the swelling was obtained in a few hours. Favourable results have also been obtained in cases of cephalalgia, otitis, angina, &c.; and, by this method of treatment, M. Gerdy considers that the influence of this pressure is the cause of inflammation in the lungs generally being situated at the base.

Tables of the Operation of Lithotomy in the Hôpital des Incurables at Naples, during Thirteen Years.

BY SALVATORE DE RENZI, M.D. A NAPLES.

Years.	Operated on		Cures.	Deaths.	A G E S.		
	Men.	Women.			Children.	Adults.	Aged.
1821	27	—	23	4	12	11	4
1822	28	—	26	2	12	12	4
1823	33	1	31	3	14	15	5
1824	35	2	32	5	15	16	6
1825	38	—	26	4	14	15	1
1826	35	2	32	5	17	17	2
1827	18	1	12	7	7	9	3
1828	25	—	19	6	10	14	1
1829	35	1	31	5	16	18	2
1830	32	3	29	6	15	17	3
1831	31	1	30	2	17	12	3
1832	22	—	17	5	14	6	2
1833	38	1	33	6	23	10	6
	389	12	341	60	185	174	42

(The above table has been verified by M. Dupuytren.)

From the preceding list it would appear that the proportion of deaths is about 1 in 7. Two of these operations were performed according to the plan recommended by Scarpa, whilst in all the other cases the lateral operation was the one adopted.

The sufferings of the different patients from the stone were dated from three months to sixteen years previous. The time in which the cures were obtained varied from ten days to a month.

In 1827 an epidemic fever prevailed, and thus accounted for more than a third part of the patients dying during that year.

In the bodies of those who died were found traces of long existing diseases, either in the kidneys, bladder, or intestines.

These statistics refer only to those who are operated on in the hospital, and are poor, badly nourished, and not well attended to; whilst the opulent are operated upon at their own houses.

Every surgeon has a right of operating in the hospital, one excepted, who has been considered incompetent. It is on this account that the proportion of deaths amount from one to seven; for those surgeons who have had much practice in this operation have only lost one out of twenty; and one of them, M. Pertrati, has lost only one out of twenty-five.—*Enc de Chiaja, No. 120.*

Table showing the Number of Deaf and Dumb Persons existing in 1830 in the Principal States of Europe.

BY E. SCHMATZ, OF DRESDEN.

States of Europe.	Total Population.	No. of Deaf and Dumb.
Portugal . . .	3,000,000	1,950
Spain . . .	10,000,000	7,150
France . . .	32,000,000	20,800
Italy . . .	20,000,000	13,000
Switzerland . . .	2,000,000	4,000
Germany . . .	41,223,000	31,657
Hungary . . .	9,444,000	6,139
Low Countries . . .	6,000,000	8,900
Denmark . . .	1,800,000	1,260
Sweden and Norway . . .	3,800,000	2,470
European Russia . . .	44,118,000	28,667
Poland . . .	5,700,000	2,405
Great Britain . . .	21,000,000	13,650

Although there is not a great difference in the relative number of these unfortunate beings in the countries here named, yet the care which is taken of them is not the same in each. In many of these kingdoms scarcely any solicitude is felt for them, and no pains are bestowed on their education; consequently they are reduced to a perfect state of imbecility. In Germany there are 48 institutions set apart for their reception, in France 26, in England 11, and in Switzerland 5; but in most of the other countries there are not more than one or two receptacles of this kind. In Russia, where there are more than 28,000 deaf and dumb, there are only two institutions.—*Gazette Médicale.*

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, February 8th, 1834.

PROFESSOR BURNETT in the Chair.

Amenorrhœa—Torsion of Arteries—New Operation, "Refoulement" of Arteries.

A GENTLEMAN related a case in which menstruation had been absent for fifteen years,

without producing any impairment of the general health.

Mr. Costello said he had met with a case in which this function was regularly performed for six months, when it then ceased for the same period.

Dr. Epps wished to inquire, whether, in the first case, there were not indications of chronic disease in some part of the body, as amenorrhœa was so frequently dependent on other affections.

The gentleman replied that he had felt the force of the remark, and had, therefore, carefully inquired into the state of the general health, but there was no symptom of disease.

The President now called on Mr. Costello for his description of M. Amussat's operation of torsion of arteries.

Mr. Costello then gave a history of the various methods, hitherto pursued of arresting hæmorrhage, and that all had repeatedly failed. He said that his friend, M. Amussat was led to the employment of torsion by accident, and after having made numerous experiments on dogs and horses, he ascertained that the operation was successful on all arteries, Mr. C. then described the operation. M. Amussat separates the artery from the cellular tissue for some distance, applies a forceps on the vessel near the heart, and another at the distal side. He excludes the blood from the portion of the vessel between the instruments, and divides the vessel between them, continuing the pressure with the instrument which is nearer the centre of the circulation. He then twists the artery several times. A spiral shaped head is formed on the extremity of the artery, composed of the cellular coat of the vessel, and there is a corresponding one formed in the retracted internal coats, which are ruptured by the twisting or torsion, and this is announced by a crack which is audible. M. Amussat had performed the operation on the spermatic artery, and next on the femoral, with perfect success. The superiority of this operation over the ligature is, the uniformity of the clot, and the practicability of the wound being treated by the first intention.

Mr. Costello then related another new operation by the same surgeon, termed "refoulement," which consists of steady pressure made with two rounded forceps, so as to divide the inner coats, which are then pushed back by the motion of the instrument, the consequence

of which is the effusion of lymph, and the obliteration of the canal.

Mr. Quain thought that torsion would be found extremely useful, particularly in those cases in which it was necessary to secure several vessels. He wished to inquire whether the clot had been seen when torsion was performed near a collateral branch, whether it was applicable to diseased arteries, and whether the refoulement had been performed on the living subject.

Mr. Costello replied, and said that clots had formed near collateral branches; he could not state whether the operation had been performed on diseased arteries, but he was able to inform the Society that refoulement had been repeatedly performed with success.

The President said that he should consider torsion a difficult operation on the vessels of an amputated stump, in which Mr. Costello concurred.

Mr. Griffiths, Dr. Epps, Mr. Hunt, and other gentlemen, made several observations.

The President observed that Mr. Costello would increase the obligations for which the Society were already indebted to him, by his performing experiments on some living animal before the meeting.

Mr. Costello said he should be happy to do so upon an early occasion.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Monday, February 10, 1834.

W. KINGDON, Esq., President, in the Chair.

Obliteration of the Medulla Spinalis, from the pressure of a Tumour, which communicated with a Cyst situated in the Thorax.

MR. ROBERTS said, that a case of paralysis, of which he had made some mention to the Society about two years since, had terminated in death; and as the post mortem examination presented some curious appearances, he would, with the permission of the President, relate the sequel. It might be remembered, that in his previous notice, in which he had traced the case to 1831, he had stated that the patient, a young female, began to lose the use of her lower extremities about five years since, retaining, however, the power of sensation for some time after the complete loss of motion.

Mr. Kingdon, who with him very carefully

examined her spine, had recommended the application of a moxa opposite the post superior spinous process of the ilium, as there appeared to be a little tenderness on pressure at that part of the canal; however, the loss of power over the lower extremities increased, in spite of all treatment, and finally her legs became quite paralysed. Incontinence of urine came on, but, by the use of tinct. lyttæ., she regained a degree of power over this organ, which, however, was lost again, if the remedy was omitted for only twenty-four hours. Notwithstanding these symptoms, her general health continued good, and the catamenia were quite regular; there was an ulcer situated at the lower part of the back, as large as a sixpence, and subsequently several others, of much larger size, were caused by pressure on the hips; others also made their appearance at the back of the knees, and even as low as the ankle. Latterly she could not be prevailed on to take medicine, but her bowels were kept in good order by glysters. She died last December, five years from the commencement of the disorder. An examination of the body was made, and the following appearances were observed. There were several large ulcers situated about the hips and parts of generation, and traces of others, which had granulated and healed, were found. The contents of the cranium appeared in a normal state, with the exception of a slight effusion beneath the arachnoid, and a trifling diminution in the size of the pons Varolii; the spine was deformed, and on opening this canal a tumour was discovered, situated between the tenth and eleventh dorsal vertebræ, which, pressing upon the medulla spinalis from the right side and from behind, had caused absorption of it at that part (*the preparations exhibiting these parts were sent round*); the tumour was situated external to the theca, and communicated with a cyst, which lay upon the diaphragm in the cavity of the thorax, but behind the pleura.

Several points worthy of inquiry arose from the consideration of this case. Probably the tumour had existed some time previous to the paralysis, and had been occasioned by the extravasation of blood, from the rupture of some small vessel, which blood had afterwards become partly organised, and partly absorbed. Another remarkable circumstance, was the condition previous to

that of sensation, since the pressure from the tumour was situated on the posterior part of the medulla spinalis. It appeared also as if granulation and cicatrization were independent of the brain, for the process of reparation went on in the sores situated on the sacrum, although there was complete division of the cord at one part. In the earlier part of the disease before the paralytic symptoms were fully developed, she went out of town, and partook of generous diet, and, on her return, found that there was entire loss of motion in her legs; plethora, induced probably by this increase in diet, might have caused more rapid growth in the tumour, which would account for the sudden aggravation in the paralytic symptoms.

Mr. Dendy made some remarks as to the practicability of trephining the spine in such patients, where the existence of such a cause of disease should be supposed to exist.

Mr. Kingdon said, that a careful examination, by pressing upon the spinous processes, had been practised, and the only place in which the least tenderness was apparent, was a little above the spinous processes of the sacrum.

Mr. Procter was of opinion that the treatment had prolonged the life of the patient, but nevertheless he questioned the utility of counter-irritation, and imagined that in cases of distortion of the spine, which had got well under the use of counter-irritation, the cure was not to be attributed to this remedy, but to the horizontal position having been constantly preserved, and strict attention having been paid to the health of the patient. A case of this kind had fallen under his notice, which had terminated in complete recovery, from maintaining this position for two years. He differed from Mr. Roberts in his remarks upon plethora, as he considered generous diet rather beneficial than otherwise, if restrained within due limits.

Mr. Kingdon said, with regard to plethora, it must be remembered, that this was not a case of diseased spine, but of a tumour situated in the canal.

Mr. Jones, in reference to the remarks on the circumstance of the pressure being from behind, whilst the anterior part of the medulla spinalis was first affected, thought that the pressure would be on that part pressed against the bone, which in this instance, was the an-

terior portion of the chord; it was a common circumstance for the base of the brain to be affected, whilst the pressure was from above; another circumstance might also account for the commencement of pressure at the part alluded to, namely, that a greater degree of pressure was necessary to destroy the powers of sensation than those of motion.

Mr. Kingdon related a singular instance of the sudden restoration for a short period of the motive powers from an emotion of joy, in a patient who had suffered from shaking palsy for ten years.

Several observations fell from different members, upon the obscurity which existed as to the conveyance of nervous influence to and from the brain; and previous to the conclusion of the meeting, Dr. Uwins and Mr. Cole made some remark upon the pernicious influence of tea and coffee.

MEDICO-BOTANICAL SOCIETY OF
LONDON.

Tuesday, February 12th, 1834.

DR. RYAN in the Chair.

British Leaf—Spurious Tea.

PROFESSOR BURNETT delivered a lecture on the detection of adulterated tea, or what is termed British leaf. He gave a minute botanical description of the various leaves detected in the spurious article, and stated that it was extremely easy to discover the adulteration. He described the anatomy of the genuine tea leaf, and that of the various substitutes for it, and clearly showed the complete dissimilarity. He illustrated the distinction by various drawings. He discovered that the leaves of the elm, the aloe, the apple, and the hawthorn, constituted the British substitute for tea. He presented several specimens of adulterated tea, and of the spurious article, and the similarity was so great, that few gentlemen in a numerous and crowded meeting could distinguish one from the other. He stated that several of the oldest examiners of tea at the India house, and others who were for thirty and forty years in the trade were totally unable to detect a mixture of tea and one-fifth of the British leaf, and that chemical analysis had also failed, because most of the constituents of the British leaves were similar to those of the genuine article imported from China. The botanist only was

able to detect the sophistication. He also stated emphatically, that the government was only anxious to protect the public from a gross fraud; in as much as three parts of tea and one of the adulterated article were sold as genuine; for example, a pound of black tea was sold for eight shillings, but if one-fourth of it was worth nothing, the buyer was cheated out of two shillings. The revenue derived from the sale of tea was about four millions annually, so that the country lost one million by the fraud under consideration. The government had no objection that persons should purchase the British leaf if they pleased, and use it in place of tea; but the fraud of vending a spurious article was not to be tolerated, more especially as it pressed most upon the poor and middle classes, who were most numerous, and the most likely to purchase the cheap article. There was a great prejudice against government prosecutions; but this was most unjust on the present occasion. The learned Professor analysed the whole of the evidence given before the late Lord Mayor (Sir Peter Laurie), and clearly proved that the Excise prosecution was very lenient, for instead of applying for an immense fine, such only was sought for as would cover the expenses.

The learned Professor next alluded to the evidence of the various medical, chemical, and botanical witnesses, about ten in number; and of these only one had tried this spurious article for a week. The individual who did so, was Dr. Birkbeck, who with his family had used it without any bad effects. The deleterious effects was not the question, but the imposition in substituting the spurious article for genuine tea. All the other witnesses had merely tasted it. He (the Professor) was on the continent when the early investigations took place at the Mansion House, and consequently was unacquainted with them. But he was requested to give his testimony, and he used every possible precaution to arrive at a correct conclusion. He mixed a portion of the spurious with the genuine article, without the knowledge of any of his family, but all pronounced the tea to be bad, or that the water poured on it had not been sufficiently boiled. One of his pupils declared that it was impossible the tea was genuine, and took the leaves out of the vessel to examine them. For himself, he felt nausea, and decidedly very different from what he expe-

rienced after the usual beverage. The learned Professor made many other interesting observations, and replied to many questions to him by Dr. Sigmond, various members of the Society, and several visitors.

The time of adjournment having arrived, Dr. Sigmond announced that the Professor of Materia Medica would prosecute the subject at the next meeting, on the 25th inst., and wished to observe, that tea would be examined immediately; and though the learned Professor had not analysed the specimen of Chinese beverage about to be introduced, could assure the Meeting it was genuine. (*Great laughter.*) The Society then adjourned.

MEDICAL REFORM CERTAIN—G RIOUS TRIUMPH OVER THE C RUPT CORPORATIONS.

THE cause of humanity and of medical science has at length obtained the attention of the legislature, through the influence of that excellent and enlightened man, Mr. Warburton. On Tuesday last, 12th inst., he moved for the appointment of a committee to inquire into the various branches of the medical profession. As he understood there was no opposition to his motion, he would not enter into details upon it." He added that complaint had been made from Dublin, Glasgow, London, and various other places in the kingdom against the medical and surgical corporations as they at present existed.

Colonel Wood opposed the motion, and signified the apothecaries' act, the poor law act, and lauded it "because it prevented persons practising as surgeons." [What a pity is to see men talking about a matter they do not understand. Every medical man knows that the apothecaries' act has no connection whatever with the practice of surgery.]

Mr. Sinclair said the profession in Scotland were in favour of inquiry.

Mr. Gillon considered that the object of the apothecaries' act was to put money in the pockets of the Apothecaries' Company, and to create an objectionable monopoly.

Mr. Littleton bore testimony to the anxiety which prevailed among the profession in Ireland on the question, and all were ready to acquiesce in any arrangement having for its object an equalisation of privileges.

the whole medical profession throughout the United Kingdom.

Mr. O'Dwyer thought it a great anomaly to have physicians re-examined by the Apothecaries' Company.

Mr. Ruthven hoped the interests of the Irish apothecaries, who were a most respectable body of men, would be protected.

Mr. Hume considered it highly absurd that regular surgeons were not allowed to dispense medicines in this country. He had dispensed medicines, and considered himself as competent to do so as any man in the land. It was highly necessary that surgeons should do so in small towns, where they were physicians, surgeons, and apothecaries. He should like to see the examination of medical men conducted in open court, as was the practice on the continent; but he was sorry to say that, with respect to medical science, this country was in a state of barbarism as compared with France.

Mr. Warburton could not agree with the gallant Colonel; it was notorious, that persons, licensed by the College of Surgeons and Apothecaries' Company, were re-examined by the Army and East India Boards, while graduates of the universities of Scotland and Ireland were exempted.

THE COMMITTEE WAS THEN APPOINTED.

The cause which we have so zealously advocated is now certain of success; and the equalisation or assimilation of the laws relating to the profession will be speedily effected.

We leave the medical corporations who have impeded the progress of science, and rendered it in a state of barbarism, to use the just language of Mr. Hume, as compared to France, to apostrophise a long farewell to all their greatness. They have thrown every obstacle in the path of zealous cultivators of medicine; they have refused them all patronage, and excluded them from all places of situation or emolument. They have given no encouragement whatever to induce men to make discoveries, but they and a clique of their relations have monopolised every thing. A Reformed House of Commons will soon teach them the important lesson,

"Patens omnibus scientia."

The following are the names of the Committee, appointed by the House of Commons, on the motion of Mr. Warburton on Tuesday, to "inquire into and consider of the laws, regulations, and usages regarding the education

and practice of the various branches of the Medical Profession in the United Kingdom."

Mr. Warburton, Lord Viscount Howick, the Lord Advocate, Mr. Littleton, Sir Robert Inglis, Mr. Goulburn, Mr. Shaw, Mr. Abercrombie, Mr. James Oswald, Mr. Bannerman, Mr. Andrew Johnston, Mr. Halford, Mr. Frankland Lewis, Mr. Hawes, Mr. O'Connell, Mr. Spring Rice, Sir Robert Peel, Mr. Hume, Mr. Clay, Mr. Robert Clive, Mr. Ewart, Mr. Peter, Mr. Strutt, Mr. Edward Romilly, Mr. Wolryche Whitmore, Mr. George Wood, Mr. Ord, Mr. Gillon, Mr. Sinclair, Mr. Baldwin, Lord Oxmantown, Mr. Serjeant Perrin, and Mr. Jephson. Power to send for persons, papers, and records. Five to be the quorum.

THE

London Medical & Surgical Journal

Saturday, February 15, 1834.

MEDICAL REFORM. — SELECT COMMITTEE APPOINTED.

WHEN, in the preceding number, we announced Mr. Warburton's notice of the motion which he made on Tuesday night last, we scrupulously used the very language attributed to the hon. member by the *Times*. A Committee to inquire into the state of the Anatomical and Medical Schools, which were the reported words of the hon. member, held out a delusive hope that the power of conferring degrees, and the ranks into which the profession is split, were matters too high or too prescriptive for the interference of the legislature. We have now the high satisfaction of finding that, whilst we gave the *letter*, we were not deceived in anticipating the *spirit* of the promised inquiry. A Select Committee was appointed last Tuesday, upon the motion of the hon. member, to inquire into the laws and regulations regarding the education and practice of the various branches of the medical profession in the United Kingdom. And, after all the vapouring of Sir Henry's organ, *confidens tui-*

August; notwithstanding the potent influence of the President himself, and his insinuating address, the government gave no opposition to the motion—nay, an influential member of the ministry hazarded his belief in the prevailing desire for a measure, the most obnoxious to the President's dearest objects of all we have had the good fortune to advocate—equality of privileges. Colonel Wood was averse to the proposed Committee; his opposition, however, was as singular as the reasons he alleged for it. The honourable member called the Apothecaries' Act of 1815 the poor man's Act. The only reason we can discover in the hon. member's speech for this soubriquet is "the well-known fact, that paupers were regularly contracted for by parish authorities!" A well-known fact it is, and well is it known also, in what manner the contract is too often performed. But why this should entitle the Act to such a charitable name is beyond our powers of comprehension. Except the useless opposition of this hon. member, *inutile Lignum*, the motion met with undivided approbation. Mr. Littleton stated, that whilst he was lately in Ireland, several deputations from the medical profession had called upon him, upon the subject of the motion, in which they all took a deep interest; and he could safely say, that, though they might not be agreed as to what measures it would be best to adopt, they had invariably expressed themselves ready to acquiesce in any arrangement, having for its object an equalisation of privileges among the whole medical profession of the United Kingdom. To one of these deputations we alluded on a former occasion. Another hon. member, in conjunction with Mr. Hume, dilated upon the absurdity of the exclusive privilege claimed by the apothecaries of dispensing medicines, to the

exclusion of the physician and surgeon; whilst they, at the same time, asserted a right of unlimited medical and surgical practice! Mr. Warburton, in fine, dwelt upon a topic often treated in this Journal,—he did not think that the certificate of the College of Surgeons, or of the Company of Apothecaries was, as regarded the holder of it, a proof of great proficiency in medical science. And the fact was, that medical practitioners, licensed by either of these bodies, were required, previous to entering into the medical department of the army and navy, or the East India Company's service, to undergo a strict examination. Such is a summary of the preliminary proceedings upon the first attempt to legislate for medicine upon general principles in this country. France has made various efforts during the last forty years to reform her medical institutions: Prussia, the last-beloved of the Gazette, has had three different codes of laws upon the subject in the same period. England has slept upon the barbarous institutions of the infancy of medicine in this country; and when she has meddled by partial legislation, she has but tangled the ill-woven web. She has now, however, the accumulated treasures of long experience, and the great exemplars of France and Prussia before her; and we doubt not she will place herself, by a strenuous regenerating effort, in her medical policy, as in her other civil institutions, at the head of the nations. For the names of the Committee we refer to another part of this Journal.

EDINBURGH UNIVERSITY.

A fortnight ago we noticed in this Journal a statement in a late publication*, to the effect that the University of

* An Examination into the Causes of the

Edinburgh had no legal power to confer medical degrees. It would be singular indeed, if, after enjoying the reputation—on the fame of which it still supports itself—of having been one of the first medical schools in Europe, the application of a little law-craft should show it has been exercising all the while an unwarranted prerogative, in bestowing degrees in medicine upon its students, whilst the undoubted privilege belongs to places having but the shadow of a school of medicine. But, when it is recollected that there never has been any systematic legislation upon medicine in these countries, and that its public laws and charters, such as they are, with scarcely an exception, are two centuries old at least, it will excite no surprise that anomalies of all kinds should be encountered. These will be proper matters for consideration at the approaching investigation.

We must now call attention to some other statements in the same pamphlet, which have attracted a great deal of notice in Edinburgh. Great dissatisfaction has for a long time prevailed respecting some recent appointments to the medical chairs of the University, and touching its general management. The precise nature of the current allegations will be found at large in the pamphlet before us. It charges, first, that appointments have been latterly brought about by corrupt influences, party feelings, and mercantile barter and sale; and again, that, in order to ensure audiences and remuneration to unqualified professors, the students have been overwhelmed with new and unnecessary classes, attendance

upon which, within the University, has been rendered imperative; and, thirdly, that the character of the examinations for degrees has been very bad, if not disgraceful to the University.

These matters within the walls have created a powerful party without, to whom the writer belongs, whose personal interests are obstructed by the monopoly of the University. The inefficiency of the public professors has raised up a body of private lecturers, unknown in the days of the Cullens, the Blacks, the Monros, and the Gregories. From a table at the end of the pamphlet, we have collected, that the extra-collegiate lecturers of the present year have nearly double the number of pupils belonging to the University classes.—The students, in fact, virtually elect their own teachers. Between these classes an irreconcilable hostility exists. The professors declare their lectures indispensable; the student finds them insufficient, and is compelled to pay his examiners, the professors, for his degree, and the private lecturers for his tuition, if, indeed, he has any cash remaining after the large drafts of the University. Not to mention the late liberal regulation of Oxford, in recognising private instruction, the mere competition of St. Andrews, where the same principle was adopted without the necessity of a degree in arts, would have soon thinned the Edinburgh University School, were she resolved to persevere in her present system. Her past course is now of little consequence, except as an item in the corporation abuses, which are soon to be detected and abated. Under better management she may again revive, and possess a school worthy of her former eminence. We are no believers in the necessity of an *aberration* of intellectual power—if we may use the expression.—The same generous and independent patronage of

Declining Reputation of the Medical Faculty at the University of Edinburgh, and the origin of another class of Medical Professors commonly called Private Lecturers; with some Remarks on the History of the University of Edinburgh. Edinburgh: 1834.

talents, which produced her former distinguished professors, is sufficient to continue their race, without consoling ourselves for their disappearance, by imagining that the splendour of genius, like the sun, must set in one place, whilst it illuminates another with its rising brightness.

The abuse of patronage, the nepotism, the monopoly, the careless examinations, the dissensions, which are the subjects of this pamphlet, are but the counterparts of what we see daily in this metropolis. We refer for details to the pamphlet, which contains some judicious observations on medical reform.

French Hospital Reports.

HÔPITAL DE LA PITIE.

Strangulated Hernia, with Perforation of the Intestines.

— DUVAL, aged 40, had suffered from hernia for four years; about three weeks before his admission into the hospital, he was attacked with colic pains, flatulence, but neither vomiting or nausea; medicines were given to him, and the pains subsided. Fifteen days after this period, without any known cause, the tumour suddenly increased in bulk, and became hard, and painful; the abdominal pain returned, and he was seized with vomiting of a green matter, which soon, however, became stercoraceous, and occurred every quarter of an hour; he remained five days in this state, being under the care of an ignorant person, when he was admitted under the care of M. Delpeau, with all the preceding symptoms, and obstinate constipation of the bowels. The operation was determined on without delay, and was performed the same day in No. 7 ward (Saint Jean); the hernia was formed by a portion of intestine of a black colour, which was perforated by three small ulcerated openings, from which escaped, at first, a reddish-coloured fluid, but afterwards true faecal matter. An appropriate mode of treatment was pursued, and with success, for although the intestine was so far advanced in a state of gangrene, no bad symptoms ensued, and twenty-five

days after the operation, the patient was discharged well.

HOPITAL DES ENFANS MALADES. *Scarlatina simulating Rubrolo at its commencement.*

— Lebel, æt. 9, was attacked on the evening of the 5th of October, with cephalalgia, slight symptoms of fever, pain in the throat, and difficulty of deglutition; on the succeeding morning he had violent shivering, vomiting, and epistaxis, the febrile symptoms were much more intense, and he became delirious; during the night an eruption had appeared on the skin.

The child was admitted into the hospital the 6th, and then presented the following symptoms, anæmia, cephalalgia, violent pulse of 120; the skin covered with a number of small red points, between which it presented its healthy colour, these spots were more numerous at the joints, than at any other part; the tongue was covered with a white coat, beneath which were seen some of the papillæ very prominent; the amygdalæ were much swollen, and deglutition was performed with great labour; the pharynx appeared red, and inflamed; the voice was hoarse; his bowels had been constipated since the commencement of the attack, but there was neither nausea, nor vomiting; he had no cough nor was there any discharge or effusion from the eyes. Borax of honey, emollient clysters, and low diet were prescribed.

7th. The eruption of scarlatina is now marked; upon the abdomen and the upper part of the thighs there is a great number of miliary vesicles; the febrile symptoms are much less violent, but the pain in the throat, and the difficulty of deglutition, still remain.

The eruption had nearly disappeared by the 10th, the febrile symptoms and pain in the throat had much abated; on the succeeding day the patient was declared convalescent.

Chronic Peritonitis—Ascites Tapped three times—Cure.

A vine-dresser, æt. 48, had for twenty years an enormous scrotal hernia, which incommoded him only on account of its weight; he had slight fluctuation in the abdomen, but no pain. M. Dubroca, of Barsac, who attended the man, considered that he had slight

scrotum, and thought that it was probably occasioned by the scrotal hernia. Some time after he was seized with violent pains in the abdomen, which was enormously distended with fluid. The operation of paracentesis was practised, and a great quantity of fluid evacuated; mercurial frictions, the internal use of digitalis, and other diuretics were prescribed. At the end of two months the same operation was again performed, and again a large quantity of serum was evacuated. In the course of two years and four months from this time, he underwent the operation of tapping twenty-eight times, in all thirty; at the end of this period the fluid was no longer secreted, and six months from this time he was convalescent. He regained his flesh rapidly, and in fact the cure was perfect.

HÔPITAL DES ENFANS TROUVÉS DES BOURDEAUX.

General Ramollissement of the whole Cerebral Mass—Altered state of the left Lateral Lobe, in which the Lateral Ventricle communicated with the internal Auditory Canal.

Hippolyte Athénée, æt. 7, of a scrofulous constitution, and a lymphatic temperament, was brought to the hospital at the age of four years. At the time of his admission, there was found at the base of the left mastoid process a fistulous opening, from which flowed a great quantity of foetid greyish coloured pus; the left side of the face was swollen, and appeared to be paralysed, and the eyelids of this side were everted. For some time before his death, the cellular membrane became infiltrated, and there was anasarca over the whole body to a great extent.

Autopsy.—A vertical section of the cranium was made, and it was then seen, that the parts in the neighbourhood of the petrous portion of the temporal bone were so extensively diseased, that it was impossible to recognize any structure; no traces were found of either the cavity of the tympanum, the small bones of the ear, labyrinth, vestibule, cochlea, or semi-circular canals; neither were there any vestiges of the acoustic nerve, but the orifice of the internal auditory foramen communicated directly with the left lateral ventricle, by means of a canal, formed in the substance of the brain, and through which the

serum of the ventricle mingled easily with the purulent matter formed in the ear; the left lobe of the lung had contracted intimate adhesions with its membranes, throughout all its extent, and the whole cerebral mass was in a state of ramollissement, and bathed in serum.

Notwithstanding this extensive disease, the external ear was in a healthy state, and the canal was perfect; much serum was found in the cavities of the thorax and abdomen, but no other appearances of disease or alteration were found in either cavity.

HÔPITAL MILITAIRE D'INSTRUCTION D'ALGER.

Two cases of Chronic Angina tonsillaris, cured by making incisions in the Tonsils.

BY M. BAUDENS, D.M.P.

G***, a soldier, belonging to the 11th regiment of dragoons, ætat. 28, had for some years suffered under chronic angina tonsillaris, which obliged him very frequently to enter the hospital. Incision of the tonsils was proposed as a remedy, and on the 20th of May, he proceeded to perform the operation of incising the glands with a double edged bistoury. He first divided the left tonsil, which was the largest, from below upwards, and then changing the bistoury into his other hand, divided the other tonsil in a similar way; the amygdalæ bled freely, and a gargle of mallows was prescribed, for the purpose of favouring the flow of blood. Eight days after the operation, this man left the hospital perfectly well.

A boy, aged 12, was attacked with chronic angina tonsillaris; since the age of five he had suffered considerably from slight attacks of this nature, and his health had become much injured. The amygdalæ were much swollen, and deglutition was, from this cause, performed with great difficulty; when the boy uttered any cries or wept, the glands approached each other and threatened suffocation; his breathing during sleep was stertorous; some months previous a sister of this patient had died from the same complaint. A few days afterwards the same operation as in the preceding case was performed, but with more difficulty, on account of the intractability of the patient. In this case, as in the former, the incision of the amygdalæ was crowned with perfect success; in a

days all the unpleasant symptoms disappeared, the glands diminished in size, and he was discharged perfectly well.

British Hospital Reports.

ST. THOMAS'S HOSPITAL.

Epilepsia et Paralysis.

SUSAN BAINBRIDGE, æt. 34, admitted October 17th, 1833, into Mary's Ward, under the care of Dr. Elliotson. Has been ill three years; has lost the use of all her limbs; her speech partially, and also her hearing, after a fit, during which she was entirely insensible. States that she has been subject to headach from infancy, but which entirely disappeared when the paralysis came on. At one time she experiences a numbness, at another, a pricking sensation, in the fingers. Has had no catamenia for the last six months, but, previously, had always regained her speech perfectly at the time of menstruation. Pupils dilated; bowels confined; tongue tremulous. Thinks her illness was brought on by sleeping in a damp bed.

Abrad. capillitium. Ung. iodinae mitius capiti bis die infricandum. Fiat setaceum per nucham. Hydr. submur. gr. v. o. n. Mist. sennae comp. manè quotidie si opus sit.

24th. Is no better; has violent fits of tremor occasionally.

Nov. 5th. Mouth sore. Omitt. hydr. submur. Cont. unguentum.

12th. Much improved; can talk better; her answers less unconnected; tongue steadier. Ordered tinct. iodinae \mathfrak{m} x. Liq. potass. hydriod. 3 j. ter die.

19th. Tinct. iodinae, \mathfrak{m} xv. Liq. potass. hydriod. 3 ij. ter die.

24th. Is able to walk by laying hold of the table, &c. to support herself. Has a greater and more perfect power of speech. The tremor of the tongue and hands is considerably less.

Dec. 1st. Continues to improve, so much so, that she hopes to spend her Christmas at home.

18th. Still better; articulates more distinctly, and does not forget her subject as formerly.

30th. Much better; can hardly be persuaded to stop in the hospital, so desirous is she of going home, declaring that she is quite well. Requires but little assistance in walking.

Jan. 6th. Can hold her hands out before her for some time without their shaking. Can walk alone.

15th. Is so much better as to be able to walk up and down stairs, and wait upon the patients. Her tongue is nearly steady; can raise her hands to her mouth and hold them there for some time. Her countenance and eyes are much brighter and clearer than a fortnight ago.

21st. Is not so well; is suffering from anxiety on account of the indisposition of her little girl. Her tremor is greater.

Feb. 3rd. Is better; gradually improving. Continues her mixture and ointment.

Morbus Hepaticus.

Richard Barrett, æt. 33, admitted Oct. 11th, 1832; a ballast gatherer, comes from Cork, where he had been accustomed to drink large quantities of whiskey. During his residence in England has drunk a pint of rum and two gallons of porter daily. The liver is exceedingly large and hard, the right lobe reaching to the superior anterior spinous process of the ileum. Has a sensation of heat in his throat; also an unpleasant taste, especially after eating. Sour liquid rising into the mouth; great flatulency and giddiness; bowels not open for the last two days; great tenderness on pressure over the loins; tongue whitish; pulse 120, hard. Ordered

Ol. crotonis, \mathfrak{m} $\frac{1}{4}$ quotidie.

Ung. iodinae abdomini bis die infricand.

Liq. potassae hydriodatis 3 ij. ter die. (Potass. hydriod. 3 j. ad aq. distill. 3 j.)

Hydrarg. submur. gr. ij. omni nocte.

Acid. hydroc. \mathfrak{m} ij. ter die ex aqua.—Dieta lactis.

13th. The food does not now turn sour on his stomach, neither has there been any rising of liquid in the throat.

16th. The dyspeptic symptoms have for the most part disappeared; bowels open four or five times daily; tongue much coated in the middle, and red at the tip; some pain in the abdomen. Omitt. ol. crotonis et ung. iodinae. Ordered

Ung. iodinae mitius abdom. infricand. bis die.

Liq. potassae hydriod. 3 ss. ter die.

19th. Much purged; stools whitish-yellow. Complains of griping. Ordered

Opii gr. j. omni nocte.

23rd. Is still very much griped and purged, and complains of tenesmus. Liver not so hard.—Omit. medicamenta. Ordered

Inf. catechu, 3 jss. cum tinct. opii \mathfrak{m} x. post sing. liquid. dejection.

Cont. opii, gr. j. o. n.

Enema amyli cum tinct. opii \mathfrak{m} xl. vespere.

26th. Still complains of tenesmus and weakness; pulse 80, compressible; liver has greatly decreased. Ordered

Enema amyli, &c. quotidie.

Ung. iodinae bis die infricand. abdom.

Liq. potass. hydriod. 3 ij. ter die.

29th. Complaining of tenesmus, and also of the great diminution of his liver. Declares that it will all waste away if he should remain longer in the hospital.

Nov. 2nd. He left the hospital this morning by his own desire, for fear lest his liver should entirely disappear.

Remarks.—The above cases, together with those of *Induratio Pulmonis*, published in No. 105, are evidence of the powerful effects which iodine possesses over the general absorbent system.

It has appeared a mystery to some, that remedies should possess the power of causing the absorption of redundant, or newly-formed growths, such as bronchocele, &c., in preference to the general textures of the frame; but as it is an acknowledged law, that all new-formed parts or growths, not constituting an original portion of the body, are endued with an inferior degree of vitality to that of parts naturally appertaining to the animal machine, it follows that such parts would be the first to give way when the whole absorbent system has been roused under a remedy so powerful as iodine.

It would be wrong, undoubtedly, to suppose that the seton has been productive of no benefit in the striking case of Bainbridge; but, independent of this, there are many cases at the hospital under the care of Drs. Elliotson and Roots, illustrative of the benefit to be derived from the employment of iodine, such as paralysis, considered to arise from morbid growths in the brain, enlarged liver, spleen, &c., and in one case, now under the care of Dr. Elliotson, of enlargement of the ovarium. It may be observed, however, that this remedy, like mercury and all others, fails to reduce hypertrophy of the heart; nevertheless, it is frequently had recourse to in conjunction with mercury, as the most probable means of effecting so desirable an object.

Although it is so largely employed at this hospital, and that in considerable doses, and even to saturation of the system, we seldom, if ever, witness those direful effects which are said to follow its use by Dr. Gairdner and others, such as absorption of the testes, mammae, &c. The only effects it is observed to produce are, occasionally, the symptoms of a mild gastritis, such as heat in the stomach and throat, but which, by a discontinuance of the remedy and low diet, easily subsides. The ointment, too, on delicate skins, at times produces considerable heat and irritation, and for which the milder one is then substituted.

In the weekly Medical Newspaper for the 30th of January, 1833, published at Berlin, is a paper by Dr. Kluge, on the effects of iodine in checking salivation from mercury. Several cases are there related, in which ptyalism speedily ceased under its administration. Dr. Graves, of Dublin, also has published an account of two cases, in which salivation was arrested by iodine. Whether further trial will corroborate the practice of these gentlemen remains to be proved, or whether there is any difference in the effects of iodine on the constitution, after salivation has been established, to that of its administration in conjunction with mercury, time must determine: but thus far we are assured; and that, from the great practice at this hospital, that mercury will cause salivation as rapidly (if not

more so) in conjunction with iodine, as when it is administered alone.

ST. GEORGE'S HOSPITAL.

Apoplexy of the Retina.

MARY FORD, æt. 32, admitted Jan. 25th. Yesterday morning, without the occurrence of any known cause, she became suddenly so blind with the right eye as almost entirely to lose the power of vision. When she applied for relief the iris of the right eye was contracted, and its margin extremely irregular, acting very little, or not at all, on the admission of light. There is a slight degree of glaucoma present, and the conjunctiva is more vascular than natural. Pulse is full but not strong. Complaints of headach; bowels regular. The menstrual discharge, which is near at hand, has always been regular, but very scanty in quantity, and dark coloured. She has been in the habit of losing blood several times in the year, but has latterly neglected to do so.

There is amaurosis of the left eye, with strabismus; she has lost the sight in it for four years. She has not been in the habit of viewing minute objects, or exposing her eyes to a strong light.

Cucurbit. cruent. ad 3 xv. nuchæ.

Hydrarg. submuriat. gr. v. hæc nocte sumend.

Haustus sennæ cras primo mane sumend.

26th. She can see better since the cupping; pulse improved, more firm and strong.

R. Hydrarg. submuriat. gr. ij.

Extract. opii, gr. ss. Bis in die sumend.

Repet. cucurbit. cruent ad 3 x.

Emplast. cantharid. fronti applicand.

Three years since she had an attack of rheumatism, followed by some affection of the eye, which was most probably iritis.

29th. R. Mist. camphor. Decoct. aloes comp. aa 3 vj. ter in die sumend.

Feb. 5th. Rep. empl. cantharid. fronti.

12th. Emplast. cantharid. nuchæ.

19th. Can see much better; the irides act more. She has had severe headach these four last days, with fluor albus.

Cataract of both Eyes.

William Wade, ætat. 70, a hackney-coachman, was admitted, under the care of Mr. Walker, with cataract of both eyes. He gives as the history of it, that about twelve months since he first found his vision impaired, and, after driving a long distance, or when exposed to severe weather, his eyes felt weak, and there appeared to be a cloud between him and his horses' heads. This indistinctness of seeing objects gradually increased until about six months since, when he could not see his horses' heads at all, and he was consequently obliged to give up his work entirely. The eyes have never been inflamed, and he suffers

no pain whatever in them or in his head. The vision of the left eye is completely darkened, but he can see sufficiently well with the right eye to find his way abroad; and he can see better in the shade than in a strong light. The cataract of the left eye is small, but completely fills up the pupil; is of an opaque yellow colour, but with some lighter streaks anteriorly, and seems firm and solid. In the right eye the opacity is not so extensive, and the lens appears of a larger size than on the left. The iris contracts readily on the admission of light; its colour and position are natural; the cornea is rather prominent, and the anterior chamber large.

Jan. 3rd. Lotio extracti belladonnæ oculo.

5th. Extract. belladonnæ supercilio nocte manèque applicand.—Omit. solutio.

19th. Ol. ricini, ʒ ss. statim sumendum.

26th. Mr. Walker operated on one eye to-day. A needle was passed through the cornea and anterior capsule of the eye to allow of the admission of the aqueous humour for the absorption of the margin of the lens.

Ol. ricini, ʒ ss. cras primo mane sumend.

28th. The anterior chamber of the eye is again filled up with fluid, but there has supervened no inflammation.

Feb. 9th. Mr. Walker intended to have performed the operation of extraction this morning, but postponed it in consequence of the patient complaining of some pain in the bowels, and vertigo following a dose of haustus sennæ.

R. Misturæ camphoræ, ʒ j.

Tinct. hyoscyami, ℥ xii. Misce, fiat haustus 6tis horis sumend.

Extracti belladonnæ supercilio applic.

10th. Better this morning. The pupil of the eye is more dilated with the belladonna. The operation of extraction was performed by making an upper section of the cornea. Some slight difficulty occurred in consequence of the incision being somewhat oblique in direction. The lens was firm and yellow.

Vespera.—No pain whatever in the eye or the head.—Perstet in usu haustus camphoræ et hyoscyami.

11th. Some pain and throbbing in the eye and temple; bowels not open; pulse full and hard.

V. S. ad ʒ xvij.

12th. Much relieved by the bleeding. Slept for four hours; some slight return of pain in the eye; bowels not open.

Hirudines xij. regioni temporali sinistro.

R. Hydrarg. submur. Pulvis antimon. āā. gr. iv. horâ somni sumend.

Ol. ricini, ʒ ss. cras primo mane sumend.

13th. No pain, but some soreness in the eye; bowels open.

R. Hydrarg. submur. gr. iv. Pulvis Doveri, gr. viij. h. s. sumend.

14th. Slept well; some slight pain and soreness in the eye; bowels not open.

Hirudines viij. parti affect. applicand. Perstet in usu pulv. horâ somni sumend.

Ol. ricini, ʒ ss. cras primo mane sumend.

Jusculo bovini, Oj. quotidie sumend.

Lotio plumbi oculo applicand.

19th. Slight chemosis; pupil round, and but a small portion of the opaque capsule hangs over its lower edge into the anterior chamber.

R. Pulvis Doveri gr. v. Hydrarg. c. cretâ, gr. ij. omni nocte horâ somni sumend.

Haustus effervescens quartis vel sextis horis sumend.

23rd. No pain, and very slight soreness; can distinguish features and objects slightly, but complains of much intolerance of light.

R. Infusi. sarsæ alkal. ʒ ij. ter in die sumend.

Repet. pulvis omni alternâ nocte.

26th. Mouth sore. He can distinguish the hands of a watch. No inflammation whatever.—Omitt. pulvis. Gargarisma a luminis.

WESTMINSTER HOSPITAL.

Compression of the Brain without bad consequences—Cura.

A very extraordinary case presented itself some time ago here in the person of a lad about twelve years of age, who met with a fall so violent as to cause an indentation in the cranium, about the junction of the frontal with the right parietal bone. The peculiarity of the case consists in the complete absence of any of the symptoms of compression of the brain. The boy suffered no ill effects whatever from the accident, nor were the constitutional functions in the least damaged. During his stay in the hospital, his head was shaved, and he was put on low diet. He was in a few days discharged, apparently in the most perfect health.

MIDDLESEX HOSPITAL.

Hæmatocele caused by the Kick of a Horse.

W. Williams, æt. 37, admitted January 18th, under Mr. Mayo. He had been kicked by a horse the day before in the groin and scrotum of the left side; the scrotum was immensely swollen and discoloured; there was no pain in the part, but a great deal across the loins, with nausea; he passed the urine freely and without pain. Spirit lotion applied to the part.

19th. Pain in the back less, and confined to the left side; considerable pain in the scrotum, the distension and discoloration being very great; it was evident that a quantity of blood was contained in the cellular membrane of the scrotum, but the state of the testes could not be determined. Two incisions were made to relieve the distension, one at the upper part,

the other at the lower and left side, of the scrotum; fomentations applied, and the scrotum supported; some blood gradually flowed from the lower incision, and the tension and pain were diminished.

20th. Much easier this morning; no pain in the loins, nor in the scrotum, unless pressed.

*Rt. Magnes. sulph. ʒj.
Liq. antim. tart. ℥xl.
Aq. menthæ pip. ʒiiss.
Fiat haust. ter die sumendus.*

25th. The pain and tension have been diminishing daily. It is now clear, that one part of the swelling arises from blood contained within the tunica vaginalis, the other and lower part, from blood effused into the cellular membrane of the scrotum.

Tunica vaginalis punctured, and eight ounces of blood, fluid and congealed, oozed out; this was followed by great relief.—Continue medicine.

February 1st. The tumour was again punctured, and ʒviij. more blood came away; this was followed by smart inflammation of the testis and cord, which was relieved by purging and the application of leeches to the groin.

In a few days' time he was so much better, that he left the hospital, the scrotum remaining swollen, but without much pain. He was directed to wear a suspensory bandage, to foment the part night and morning, and to return in case the pain increased.

Case of Varicose Veins successfully treated by the application of Caustic Issues.

Mary Walton, ætat. 39, admitted October 22, 1833, for a varicose state of the internal saphena vein, extending from the inner ankle to the middle of the thigh; the vein gradually enlarging from the ankle, and becoming, at the inner condyle, so much enlarged as to form a considerable projection, the vein being at least as large as a man's thumb, and exceedingly convoluted.

The disease came on about seven years ago, and soon afterwards an ulcer formed at the inner ankle, for which she received medical treatment; the ulcer remained open four months and then healed; the vein, however, increased in size, and has continued to do so to the time of her admission. The ulcer has repeatedly returned, never remaining healed more than two or three months at a time, but continuing open at least four.

The leg was at first bandaged for a short time, and then two large caustic issues were made across the course of the vein, one in the middle of the thigh, the other half way down the leg.

Nov. 22nd. Sloughs from the issues came away; the leg is very stiff and painful, the vein being swollen in size, but hard and distended, and exceedingly tender on pressure.

30th. Vein much swollen, and also less painful; the leg is still stiff, has become

slightly contracted, and cannot be straightened without giving very great pain.

Ordered to endeavour to bring the leg gradually straighter, and to have another issue made across the vein just above the situation of the ulcer.

Dec. 16th. Able to straighten the leg entirely; veins not above a quarter the size they were previous to the application of the issues; no pain in the veins unless pressed upon, they however still feel quite hard.

25th. Issues just healed; veins less and softer.

From the time of the issues healing the leg has been rolled, and pledgets of lint dipped in equal parts of tincture of myrrh and lime-water applied to the situation of the issues.

She has now left the hospital experiencing no pain in the veins from pressure or otherwise. The vein is completely obliterated at the points where the issues were made; nevertheless, after standing, it is slightly distended, by the blood flowing into it from collateral communications; it is not more than one-sixth of its size at the time of her admission.

With respect to the application of caustic issues in these cases, causing phlebitis, Mr. Mayo stated, that he had now applied them in numerous cases, and with different degrees of severity, even to producing sloughing of the vein itself, but that in no case had the practice been followed by phlebitis. Mr. Mayo does not recommend this practice indiscriminately; the constitution and age of the patient, the number of nervous trunks affected, are the principal points which have to be considered, and upon which the expediency of the practice turns.

Fragilitas Ossium.

Richard Holman, æt. 41, admitted under Mr. Mayo, Dec. 5th, for fracture of both thighs occasioned by catching his toe against a projecting part of the pavement while walking leisurely along.

He has a large head, light hair, fair complexion, prominent large eyes, and a high narrow chest.

This patient in the year 1821 fractured the tibia and fibula of the left leg, by merely kicking his foot against some projecting substance.

In the year 1828, he broke his left thigh, by catching his toe as he was going up stairs, and again in the year 1830, treading on a bean shell, slipped down, and fractured his right thigh.

The thighs were bandaged up with Desault's splints, which were removed Jan. 27th, and each thigh then done up with empl. saponis, three small deal splints, and bandages.

BOOKS.

THE Anatomy and Surgery of Inguinal and Femoral Hernia. Illustrated by Plates coloured

from Nature. By E. W. Tuson, Esq., F.L.S. Assistant Surgeon to the Middlesex Hospital. Folio. Five coloured Plates. London: 1834. J. Churchill.

This work admirably illustrates the anatomy and surgery of Hernia.

The Anatomy and Physiology of the Liver. By FRANCIS KIERNAN, Esq., late Teacher of Anatomy. (From the Philosophical Transactions.) 1833.

CORRESPONDENTS.

Dr. O'Beirne.—It is quite impossible for us to insert another long reply to Mr. Salmon at present, as we cannot allow a controversy of this kind to occupy several numbers of our Journal. Dr. O'Beirne's reply has already occupied eight pages of small type, or one-fourth part of one of our numbers; and were we to continue controversial articles of such length, we should exclude a mass of diversified matter, much more important and instructive to our readers. Mr. Salmon has claim, as a matter of right, to repel some extra-medical charges made by Dr. O'Beirne, which must be the last communication on the subject. On the matter in dispute we entertain our opinion expressed in our Journal of No. 97, Dec. 7.

Beroliniensis.—The Prussian medical code has been grossly misrepresented in the article alluded to; more of this in our next.

Mr. R.—We shall be happy to receive such communications, and shall print them at our earliest convenience.

Mr. Wilkins.—The article has never reached us.

Medicus.—We shall insert the article on Vesical Medication in an early number.

Mr. Bacon's communication in our next.

VOL. V.

LECTURES
ON THE
PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,
BY PROFESSOR SAMUEL COOPER.
*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXVII., DELIVERED MARCH 28, 1833.

GENTLEMEN,—Let me next call your attention to *scrofulous abscesses*. I have mentioned, as one of the common effects of scrofula, a tendency to the formation of chronic abscesses in various parts of the body. Those occurring in the absorbent glands I have already described. A propensity to indolent suppuration you will see also exemplified in the discharges from the ears, so frequent in scrofulous subjects; and a similar disposition to chronic suppuration is manifested in the formation of large indolent collections of matter in the cellular tissue of different regions of the body, but, more especially, in the cellular membrane situated between the peritoneum and the muscles of the loins. These last cases are well known to surgeons under the name of *psoas*, or *lumbar abscesses*. I believe they deserve the appellation of *scrofulous abscesses* fully as much as those more common suppurations of the glands at the side of the neck and under the jaw. These chronic collections of matter, arising from scrofula, usually come on without much pain, and sometimes attain a considerable size before the patient's notice is attracted to them. However, if an opening be not made in them, they continue to increase in size, and at length they constitute truly formidable diseases from their mere extent. In this condition, they usually create a hectic disturbance of the system, and are attended with more or less pain and inconvenience.

Gentlemen, it is useful to recollect, that many scrofulous abscesses do not begin with disease of the soft parts, but with disease of the spongy parts of the bones. We know that lumbar abscesses are sometimes connected with such a cause; we know that the abscesses about joints are often induced in the same

way, as well as those scrofulous suppurations which arise around the phalanges of the fingers, and within the tympanum of children.

I have described the lymphatic glands as most liable to scrofulous disease in persons under puberty; and in individuals past this period of life the lungs to tubercular affections, constituting the most fatal form of phthisis pulmonalis, which I regard as a scrofulous complaint.

Tubercles, or the tubercular formations, consisting of a greyish, semi-transparent, caseous, unorganised substance, are now generally admitted to be of a scrofulous nature; and though Dr. Abercrombie found, by chemical analysis, some differences between the constituent parts of scrofulous glands and pulmonary tubercles, Professor Carswell tells us, in his *Illustrations of the Elementary Forms of Disease*, that he has detected the tubercular deposit in abundance, both in the lymphatic glands and in those of the mesentery, when enlarged in consequence of scrofulous disease.

Now, you should understand, gentlemen, that the lymphatic glands are frequently affected only secondarily. Thus, in children who have porrigo, the irritation of that disease very often gives rise to glandular enlargements at the side of the neck, which may assume a scrofulous character. When the glands of the mesentery become the seat of scrofulous disease, it is often in consequence of a diseased state of the mucous membrane of the bowels. In the same manner you will find the glands under the jaw becoming enlarged, not only from porrigo, but from the irritation of catarrhs and common sore throats. Scrofulous swellings of the glands of the groin and arm-pit are often preceded by disease of the joints, or irritation in other parts of the limb.

With regard to the *predisposing causes* of scrofula, I may observe, gentlemen, that some peculiarity of constitution must be a predisposing cause of scrofula: this is a fact, of which no medical practitioners now entertain any doubt, though it may be difficult to define precisely what is the nature of such peculiarity. The appearances, which usually denote its existence, I have already described. I fully

coincide in the observation, that each individual has something peculiar to himself in his bodily organisation; that there are infinite varieties of natural organisation in the human species; and in individuals, who are distinguished by some of them, there is a greater or less susceptibility of particular forms of disease.

Much controversy has taken place on the question, whether scrofula be an *hereditary* disease or not; but, I believe, now that mutual explanations have been given, little or no differences of opinion remain on this point. All that is here meant by the expression *hereditary* is, that the children of scrofulous parents are more likely to suffer from scrofula than the offspring of persons who have always been perfectly free from that disease. That scrofula prevails a good deal in certain families, is the utmost extent to which it was ever designed to carry this doctrine. It was never intended to assert, that there were not exceptions to this general observation; and what man of experience and observation does not know, that the children of scrofulous parents frequently continue, as long as they live, entirely free from the disease? On the other hand, the most healthy parents sometimes have scrofulous children. If any further proof were required of children being occasionally brought into the world with a predisposition to scrofula, derived from their parents, we might, perhaps, find it in the fact of their being occasionally born with scrofulous tubercles already formed.

Amongst the *exciting causes* of scrofula are usually specified various circumstances tending to produce debility, or, at all events, to leave the system in a seriously disordered state;—such as fevers from contagion of a specific kind, like measles, scarlet fever, and small pox. Hence, previously to the introduction of vaccination, by which the evils of the small pox were so much diminished, it is in the recollection of many experienced practitioners still living, that scrofula prevailed even to a greater extent than at the present time.

Of late years, scrofula and many other diseases have been ascribed to disorder of the digestive functions, little trouble being taken to consider fairly, whether such disorder may not be rather the common effect or accompaniment of such diseases, than the cause of them. To say that there is always and essentially more or less disorder of the digestive organs in scrofula, and *primarily of no other important function*, as is sometimes maintained, seems a perfect absurdity, an hypothesis that could not be reconciled with the fact recorded by the very persons who broach it, namely, the occasional existence of scrofulous disease in the *fœtus*. While we find that, in a given number of children living together in the same atmosphere, under the same roof, feeding and sleeping together, and clothed exactly alike, only one or two become scrofulous, while all the others continue perfectly free from the disease, we must admit the impossibility of accounting

for the production of scrofula by the hypothesis in question. We are again compelled to return to predisposition, and original kind of constitution, as a solution of the difficulty.

With the admission of a predisposition to the disease, some peculiar state or modification of the animal economy, original or acquired, and the essence of which at present eludes our investigations, various influences may become exciting causes of scrofula, and perhaps the operation of climate is the most powerful; for we find that scrofula is chiefly confined to countries which are remarkable for their damp, cold, and variable atmospheres, as Great Britain, Holland, and the northern parts of Germany and France. Persons living in the extremes of heat and cold, are much more rarely affected; but, no sooner do they come to this country, than they are even more liable to scrofula than other individuals.

Every surgeon is aware, gentlemen, of the great liability of children brought from the East or West Indies to scrofulous diseases, and of the African blacks and natives of the South Sea Islands to tubercles when they come to this climate. The monkey, also, a native of warm parts, is in a similar case.

Notwithstanding the general truth of this view of the comparative rarity of scrofula in hot or extremely cold countries, it is certain that the disease, and even this in its worse or tubercular forms, is a source of considerable mortality in Italy, Spain, Portugal, Minorca, Malta, and several other countries, whose shores are washed by the Mediterranean Sea. In these parts, indeed, tubercular phthisis is so prevalent and fatal, as to keep up the erroneous notion of its being a contagious disorder.

In consequence of the influence of damp and cold in promoting scrofula, patients generally suffer more in one season of the year than another, their complaints being worse in the winter and spring, and better in the mild dry weather of summer and autumn.

Besides climate and atmospheric influence as an exciting cause of scrofula, we must reckon, as tending to produce the same effect, *where the constitutional predisposition, and the influence of climate are also in operation*, improper or insufficient diet, neglect of regular exercise, bad nursing, insufficient clothing, inattention to cleanliness, and the residence of children in badly ventilated, crowded dwellings. Hence the frequency of scrofula amongst the children who work for many hours crowded together in the unwholesome atmosphere of different manufactories, often badly fed, and deprived of that beneficial influence which due exercise in the open air would have upon their digestive, cutaneous, and muscular systems. Hence, also, one explanation of the reason why infants, as long as they continue at the breast, are less commonly attacked with scrofula than afterwards: their nutriment is what nature intended for them; and, while thus maintained under such maternal care, they are

in general also not exposed to damp and cold, but sufficiently protected from these influences on their constitutions. Were I to judge from the extent of scrofula which I notice amongst the children of the poor Irish brought to the Bloomsbury Dispensary, I should incline to the belief, that the various causes which I have specified may not only excite scrofula, when a predisposition to it exists, but even engender those peculiarities of constitution, without which the human system appears to be hardly susceptible of the disease.

Treatment.—Gentlemen, it is only necessary for me now to offer a few general observations on the treatment of scrofula, because the practice, which is applicable to some forms of the disease, is more conveniently brought under consideration in other lectures. Thus, I have already explained the mode of treating scrofulous joints, and the practice in scrofulous affections of the spine, thyroid gland, and breast, and the principles on which the psoas abscess ought to be treated, I shall mention in the future lectures.

When you remember the circumstances, which operate as the existing causes of scrofula, you must immediately see, that one of the chief means of obviating that morbid condition of the system, which accompanies scrofula, is the removal of the patient from the influence of such causes. If he be residing in a damp, cold, badly ventilated, crowded place, he should be immediately taken from it. If his diet be faulty in point either of quality, or quantity, it should be rectified. If his clothing be insufficient to protect him effectually from the influence of damp, and of sudden changes of the atmosphere, it should be improved and made warmer. If the patient be a child, kept in a sedentary state, working in some crowded manufactory for a great part of the twenty-four hours, it should be taken from such employ and place, and allowed to have the benefit of a salubrious air, and healthy exercise.

The doctrines of the late Mr. Abernethy make the principal indication in the treatment of scrofula to consist in aiming at the improvement of the state of the digestive functions. While I do not admit the truth of the theory that the origin of scrofula is essentially dependent on disorder of the digestive organs, I fully agree in the prudence of the advice that we should always endeavour to restore the natural and healthy functions of those important viscera, when in any respect deranged. This indication, in fact, had not been neglected by practitioners who lived half a century ago. Whoever compares the practice of Mr. Charles White in giving small doses of calomel, occasional purgatives, and the simple or compound decoction of sarsaparilla, with the blue pill, sarsaparilla, and laxative treatment, of Mr. Abernethy, will see no very material difference between them, especially when the stress which Mr. White laid upon attention to diet, clothing, avoidance of damp and cold, and the usefulness of good air and regular exercise, is

taken into the account. Mr. Abernethy's practice consisted in giving five grains of the blue pill every night, and half a pint of the compound decoction of sarsaparilla twice a day; and, if no motion took place by a certain hour every day, some aperient medicine was administered.

The plan was followed up until the bowels became regular, and then, with the view of preventing a relapse, five grains of the compound calomel pill were given for an indefinite time. When acidity prevailed, small doses of the carbonate of soda were prescribed, and, when the stomach was weak, and the appetite bad, bark, steel, and the mineral acids were recommended.

A light nutritious diet is generally found to agree best with scrofulous patients; but it should not include wine and porter, unless the forms of disease, under which they are labouring, are attended with profuse suppuration and hectic debility.

Sometimes, gentlemen, when the tongue is foul, the breath bad, and the belly tumid, it is advisable to let the treatment commence with brisker purgatives, as jalap and scammony, or the compound powder of scammony, or James's powder and calomel. Such medicines may be given in proper doses at night, and their operation promoted with the senna mixture, or castor oil, on the following morning.

The bowels having thus been well opened, you may next employ milder medicines of the aperient and alterative kinds, as rhubarb and the subcarbonate of soda, to which a small quantity of mercury with chalk may be added.

Then, with such treatment may be combined, after a short time, the employment of tonic medicines, as the infusion of cascarilla, the sulphate of quinine, and other preparations of bark, or the infusion of calumba, with or without the tinctura ferri muriatis, or you may prescribe the compound infusion of gentian with the subcarbonate of soda; or else the compound decoction of sarsaparilla, with the diluted nitric or sulphuric acid. Those who believe in debility, as essentially conducive to the origin of scrofula, place their dependence on tonics, and especially bark, quinine, steel medicines, and cold sea-bathing. If the skin be dry, you may prescribe antimonials.

Mercury has sometimes been decried as decidedly injurious to scrofulous patients; but this is only a prejudice, apparently derived from old notions about debility. Mercury in small alterative doses is often beneficial, and in scrofulous ophthalmia, even the free use of it is one of the best means of removing the opaque substance sometimes effused in the cornea.

The fear of prescribing mercury to scrofulous patients has now, however, nearly subsided, and surgeons frequently prescribe, besides the preparations I have mentioned, the oxymercurate, 1 gr. of which is dissolved in an

oz. of the tincture of bark, and given in the dose of a teaspoonful, three or four times a-day.

All the foregoing plans are founded upon the aim of improving the health in general, and do not embrace the idea of combating scrofula with any specific.

Gentlemen, amongst the medicines which have attracted celebrity for their supposed specific virtues against scrofula, I have to mention to you conium, or hemlock, the muriate of lime, the carbonate of soda, and preparations of iodine. As for hemlock, it has now lost the reputation of being a specific, though sometimes prescribed in equal proportion with the compound calomel pill as a useful alterative.

The muriate of lime, I believe, is at present completely out of use and favour.

The carbonate and subcarbonate of soda are undoubtedly useful medicines, but not entitled to be regarded as possessing any specific power over the disease. They are often joined with rhubarb and a few grains of the hydrargyrum c. creta, or with rhubarb and cascarrilla; which formulæ are sometimes beneficial as alterative medicines, but nothing more.

With respect to iodine, it is at present in considerable repute, and as employed by Dr. Lugol, Physician to the Hôpital St. Louis, at Paris, seems to possess great power over scrofulous diseases. For this purpose, Dr. Lugol employs certain preparations of iodine, some of which are intended for internal and others for external use. They are different from those which are employed in this country; more numerous, and if the report made to the Academy of Sciences by Serres, Magendie, and Duméril, can be credited, far more efficacious.

For internal use, Dr. Lugol prescribes iodine dissolved in distilled water by means of the hydriodate of potash. He has three solutions. of different degrees of strength.

No. 1 contains $\frac{1}{4}$ of a grain of iodine, $1\frac{1}{4}$ grain of hydriodate of potash, in 8 oz. of distilled water.

No. 2 contains 1 grain of iodine, 2 grains of hydriodate of potash, in 8 oz. of distilled water.

No. 3 contains $1\frac{1}{4}$ grain of iodine, $2\frac{1}{4}$ grains of hydriodate of potash, in 8 oz. of distilled water.

Children take these preparations readily when a little sugar is added to them, which should be done at the moment before they are taken, because if the sugar be put into the solution sooner, it changes the colour of the mixture, and destroys its activity.

Dr. Lugol begins with giving one-half of a grain of iodine in the twenty-four hours, and therefore lets the patient have two-thirds of No. 1 in two or three divided doses.

In a few days, the quantity is gradually increased to one grain a-day, and this dose is generally continued to the end of the treatment. In some instances Dr. L. has given one grain and a half in twenty-four hours, but this

is the greatest quantity ever prescribed by him.

For making the above *iodine mineral waters*, as Dr. L. calls them, he employs a concentrated solution of iodine, composed of

℞j. of iodine,
℞ij. of hydriodate of potash, and
℥viij. of distilled water.

This concentrated solution is also itself prescribed in the dose of six drops twice a-day, gradually increased by two drops a-day every week, until the quantity amounts to thirty or thirty-six drops in twenty-four hours; to be taken in a little water sweetened with sugar, or syrup. The giving of iodine by drops he deems less exact than the use of the weaker solutions.

The *external use of iodine* may be either *local*, as when it is applied to scrofulous swellings, or to scrofulous eyes, or *general*, as when the whole body is bathed in a solution of iodine. Now, one principle, which Dr. Lugol insists upon, is, that all iodine applications not only have a specific effect on the part, but have an internal influence on the system, in consequence of absorption.

The *iodine ointments*, used by Lugol, are of four different strengths:—

No. 1 composed of

gr. xii. of iodine,
℞iv. of hydr. of potash,
℥ii. of lard.

No. 2.

gr. xvij. of iodine
℥ij. of hydr. of potash,
℥ij. of lard.

No. 3.

gr. xxi. of iodine,
℥iiss. of hydr. of potash,
℥ij. of lard.

No. 4.

gr. xxiv. of iodine,
℥iiss. of hydr. of potash,
℥ij. of lard.

These ointments should always be prepared fresh for use. Scrofulous glands, or joints, may be rubbed with them; and scrofulous ulcers and cutaneous affections dressed with them.

Ointment of proto-ioduret of mercury is another formula for external use, composed of

℞ij. of the proto-ioduret,
℥ij. of lard in No. 1,
℞ij. in No. 2, } to ℥ij. of lard.
℞iv. in No. 3, }

Dr. Lugol finds these preparations less irritating than the iodine ointment used for scrofulous cutaneous affections.

Lugol's *solution of iodine* for external use contains

gr. ij. of iodine,
gr. iv. of hydr. of potash,
in lb. j. of distilled water.

This he uses as a collyrium by means of an eye-glass, or syringes, also as an injection for

the nose, when there are scrofulous ulcerations of the mucous membrane, and for scrofulous fistulae.

Dr. Lugol employs occasionally what he terms the *rubefacient iodine solution* made of

3iv. of iodine,
3j. of hydr. of potash, and
3vj. of water.

With this he touches scrofulous ulcers, swellings, and cutaneous affections, when they require stimulation. In chronic inflammation of the eyes and eye-lids, he also applies it over the eye-lids and angle of the eye, by means of a bit of lint dipped in it.

The rubefacient iodine solution is also employed for diminishing the irregularities of the cicatrix of scrofulous disease.

Local iodine baths for the foot, hand, or chin, are made by adding a certain quantity of the rubefacient iodine solution to warm water in a tub, or wooden bowl.

When iodine is to be applied in the form of a poultice, this is made in a glazed earthen vessel, and, when sufficiently cool, the rubefacient iodine solution is added to it, and the quantity measured with a wooden spoon.

After puncturing indolent scrofulous abscesses, Dr. Lugol injects into their cavities, two or three times a day, an iodine solution. Then he rubs the skin over the abscess with the ointment of iodine, or that of the proto-ioduret of mercury.

Lugol's iodine caustic consists of

Iodine, 3j.
Hydr. of potash, ℥ā
Distilled water, 3ij.

His *iodine baths* are made by dissolving 3ij. or 3iij. of iodine, with rather a larger proportion of hydriodate of potash, in a few ounces of distilled water, which are then put into the bath. Though rather less than one grain of iodine to about a pint and a half of water, its effect on the skin is very active and sometimes reddens it.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street,
Dublin.—Session 1833–34.

LECTURE IX.

Treatment of Ileitis.—Muco-Enteritis.

GENTLEMEN,—We shall be occupied to-day in considering the treatment of inflammation of the mucous membrane of the small intestine. You may recollect, that at my last lecture I spoke of the employment of laxatives in this disease, and mentioned that we are to employ laxatives in enteritis, on the same principle as emetics are used in cases where corrosive

poison has been taken into the stomach. We are not to expect to be able to cure the disease by the use of laxatives, nor are we to have recourse to them in every case; we employ these remedies where we have decided evidence of the existence of offending matter in the bowels. We may meet with a case in the early stage under such circumstances, that the removal of the irritating matter by judicious purgation may completely relieve the patient, and this, I believe, is the foundation on which the superstruction of the British purgative practice in ileitis and tabes mesenterica was raised. It was concluded, that a laxative treatment, which had on many occasions succeeded in removing the first symptoms of the disease, would necessarily cure it in all stages and cases. This, I need not tell you, is wrong. Whenever you give purgatives or laxatives in enteritis, bear this in mind, that the effect which you have to produce is to be brought about at the least possible risk. If you can unload the bowels with a little castor oil or rhubarb, or some mild neutral salt, it is much better than to have recourse to calomel, or scammony, or colocynth. As a general rule, drastic purgatives must be avoided in inflammation of the mucous membrane of the intestines. The school of Broussais committed an error, on the one hand, by never admitting the use of laxatives, and British practitioners have been wrong, on the other hand, by giving too much purgative medicine. The error of the latter arose from looking always upon purgatives as antiphlogistics, which they are certainly, so far as they contribute to relieve inflammation by causing an increased secretion from the intestinal mucous surface. But this increase of secretion can be produced only by stimulating the organ to which they are applied; and hence, before they can become general antiphlogistics, they must, of necessity, be local stimulants. Further; if in a case of inflammation of the digestive tube you prescribe a purgative, and it fails in causing an increase of secretion, it will add considerably to the existing inflammation. It is, however, of very great importance that there should be no accumulation of offending matter in the bowels; and hence, when you find a degree of fulness in the belly, and the dejections scanty, you should always give a laxative, and follow it up by the administration of a narcotic. By using enemata, you can do a great deal of good, and this without any injury to the digestive tube; and I think they may be always employed with benefit in disease affecting the ileum. Recollect, gentlemen, what I wish to impress upon you respecting this part of the treatment is, that laxatives are to be employed in ileitis as one of the means of cure; but you are not to expect that a cure by the use of these alone will always be a matter of constant occurrence. It is true, that many cases presenting symptoms of enteritis, have, in the beginning, yielded to laxatives; but it is true also, that horrible mischief

has been done by their continued or indiscriminate employment.

A few observations now with respect to bleeding. There is in simple inflammation of the mucous membrane of the intestines this peculiarity,—it very seldom happens that it is necessary to use the lancet. The whole class of intestinal inflammations is so generally accompanied, even in the early period, with marked prostration and a typhoid condition of the whole system, that general bleeding is very seldom employed. But when the disease is recent, the constitution vigorous, the patient young, the skin intensely hot, and the pain violent, (a combination of circumstances which is not of very common occurrence) you may employ the lancet with safety and with great advantage to your patient. But what I wish to impress upon you is this,—you must not expect to cut short an attack of enteric inflammation by general bleeding. Over inflammations of mucous membranes in general, but particularly of the intestinal mucous surface, the lancet has comparatively but little direct power; it is in the inflammatory affections of parenchymatous tissues and serous membranes, that we generally observe the most brilliant and decided effects of venesection. Neither can you, as in parenchymatous inflammation, bleed a second and a third time with benefit. In cases of inflammation affecting the mucous membrane of the intestinal canal, you are to look upon venesection as a preparatory step to leeching. Where the pain is violent, the fever high, the attack recent, and the constitution strong, you will do well to bleed; but only bleed once, and then apply leeches in abundance over the suffering organ. There is nothing of more importance, nothing of such decided value, as bleeding by leeches in inflammation of the mucous membrane of the intestinal canal, and here we arrive at a fact, the explanation of which is involved in much obscurity. A patient is attacked with inflammation of the mucous membrane, and glands of the digestive tube, twelve or twenty leeches are applied to the integuments of the abdomen, and their application is followed by extraordinary relief. This is a very curious fact when we consider that between the place where we apply the leeches, and the tissue which is affected, there intervene skin, cellular membrane, superficial fascia, cellular membrane again, deep-seated fascia, muscular substance, cellular membrane again, two layers of peritoneum, and muscular substance enveloped in cellular tissue. Yet, notwithstanding this extraordinary succession of tissues, it is an undeniable fact, that the application of a dozen leeches to the surface of the belly will frequently cut short an intestinal inflammation, or materially diminish its intensity. Here is a fact, the explanation of which is extremely difficult; and I tell you candidly, I cannot explain it. The school of Broussais attempt to explain it as follows. They state that it is

a constant law of the economy, that there is a strong sympathy between the internal parts and their respective integuments, but they do not say why this sympathy should exist. We frequently, however, observe facts confirmatory of this law; you are aware that it often happens that, in cases of the deep-seated muscular phlegmon mentioned by Mr. Crampton, in abscess of the liver, and in empyema, we have a swelling of the integuments, showing the existence of a sympathy between the integuments and the internal organs.

In treating a case of inflammation of the small intestine, I think you may generally commence with the application of twelve or eighteen leeches over the ileo-cæcal region. The ordinary result of this application is, that the pain and tympanitis are reduced, and the thirst diminished; but the patient still has fever, and you are to bear in mind that the mere subsidence of pain does not imply the removal of the disease. We may modify the character of an ileitis very considerably by a single application of leeches, but we are not on that account to expect that we shall be able to remove the disease entirely. In general it is necessary to apply them two or three times, lessening the number at each succeeding application, and taking care that they are applied in the proper place, that is midway between the umbilicus and the crest of the ileum. Many practitioners are afraid of employing leeches in the advanced stage of this affection, in consequence of the great debility which characterises the advanced stage of this, as well as inflammation of every other, part of the digestive tube. But though I am quite of opinion that the school of Broussais is wrong in using them at any period, still I think they may be employed even where the disease is advanced, *particularly if they have not been used before*, and I have frequently seen leeches applied with advantage as late as the twelfth day. I have employed them myself in the Meath Hospital, as late as the ninth and tenth days, with decided benefit. Many physicians on the continent are in the habit of treating inflammation of the digestive system by the application of leeches to the anus, and this is said to have a very good effect, and the number of leeches required is smaller. In disease of the great intestine accompanied by diarrhoea, tenesmus, and tormina, I think this is an excellent mode, but when the disease is in the upper part of the tube, I prefer applying them to the belly over the situation of the inflamed organ.

Now with respect to internal medicines. In this disease every thing that is administered should be given with the view of removing irritation, and for this purpose I know no better preparation than a combination of ipecacuanha and opium, as in Dover's powder. The exhibition of the compound powder of ipecacuanha is attended with decided advantage. You are all aware of the long established use of ipecacuanha and opium in

diseases of the intestinal canal, and I think there can be no doubt that they possess considerable utility. With this I generally combine some mild mercurial; the best you can employ is the hydrarg. cum cretâ. Give two or three grains of each every second or third hour, as the case may be, and you may continue this for several days. Where there is no diarrhoea, and the bowels have a tendency to be constipated, it will be necessary to order, every second or third day, a mild laxative, a little manna, or rhubarb, or some castor oil; you should insist on the daily use of enemata, and if they answer the purpose sufficiently I would advise you to be sparing of the use of laxatives by the mouth. In addition to these remedies, I am in the habit of giving a considerable quantity of gum Arabic, which appears to have an extraordinary efficacy in disease of the small intestine. I look upon it as peculiarly valuable in the diseases of children. The ordinary mode of prescribing it is to give a certain quantity of gum water. If this is insufficient, you should order half an ounce or an ounce of the gum to be dissolved in a pint or quart of water, which the patient is to use during the day. After the use of the hydrarg. c. cretâ and Dover's powder, this has a decided value in the treatment of ileitis.

In this way, by leeching, mild laxatives, prescribing mercury with chalk, and compound powder of ipecacuanha with gum water, your patient begins to improve. The tenderness of the epigastrium disappears, the tongue begins to clean, the fever diminishes, the thirst goes off, and appetite returns. This is the favourable termination. When the patient is of a weak and delicate habit, it is of great importance to pay particular attention to supporting the strength, *even from an early period of the disease*. In such a case, after the first week, the physician who neglects the proper means of supporting his patient's strength does wrong, and it has been justly remarked, that a practitioner will be right in supporting the general strength, at the same time that he is employing local antiphlogistics. It is in steering clear between these two opposite dangers that the judicious practitioner is seen; he does not allow his patient to die of inanition, while at the same time he takes care to remove local inflammation. I have seen several experienced physicians prescribe leeches to the abdomen on the same day that they ordered the patient to have chicken broth, and even a little wine. There is nothing improper in this; an inexperienced practitioner, who has his eye merely on the local inflammation, is apt to fall into the error of overlooking the constitutional debility, and allowing it to steal upon him. He finds very little difference between the appearance of his patient this day and the next, and thinks the slight increase of debility undeserving of any attention. At last his patient begins to sink visibly, he gets alarmed and has recourse to stimulants, but it is now too late. Besides, there are several articles

of diet which support strength, without increasing inflammation, as for instance, chicken broth, sago, arrow-root, strained rice, &c. These do no harm, and they prevent the patient from falling into a dangerous typhoid condition. Let us look at this in another point of view. Suppose you are called to a child who is said to have had an attack of worms, or bilious derangement, or that his bowels were costive, and purgatives were given, that the discharges were found to be bad, and more purgatives were administered; or suppose you are called to a child of a weak scrofulous habit, who has been taking large quantities of purgative medicine, for what has been termed *derangement of the bowels*, and you find the little sufferer with pale, shrunken face, a black circle round his eyes, cold extremities, rapid faltering pulse, great thirst, and evident symptoms of increased cerebral excitement; the little arms and hands are cold as death, but the belly burning, tympanitic, and very sensible to pressure, and when you compare the radial artery with the femoral, as it turns over the pubis, you will have some conception of the excited condition of the abdominal vessels; and in addition to this train of morbid phenomena, you find there is suppression of urine. Are you to attack these symptoms with antiphlogistic means? No; the first thing you are to do, is to prevent any farther mischief, by totally inhibiting every kind of purgative medicine. You are next to consider carefully what the best line of treatment to be pursued is, for here you are under circumstances of difficulty, and have a great many prejudices to contend with. What I find generally to be most successful is this. I begin by taking proper steps to support the strength, ordering the patient to take chicken broth, arrow-root, or jelly; the extremities are to be wrapped up in warm flannel; and if the patient is sinking, and has his mouth and teeth crusted with dark sordes, a little wine, watching its effects. If it produces sleep, if the pulse comes down under its use, and the fever is not increased, it will do a great deal of good, and you can gradually increase the quantity. Always bear in mind, that there is a certain period in all inflammations, in which stimulants prove to be antiphlogistics, a circumstance which has been overlooked by the school of Broussais. So far with respect to constitutional treatment; but what will you do with local disease? The application of blisters is of decided use, nay, I have seen a few leeches very effective. Apply a blister to the abdomen, and dress it with mercurial ointment, at the same time, you may employ frictions with mercurial ointment: you will also swathe the belly with flannel, so as to keep up a comfortable temperature. In this way you will be able to do a great deal of good. You will also prescribe hydrarg. c. cretâ, with Dover's powder; and if the bowels are confined, emollient injections. By steadily pursuing this plan of treatment, you

will often rescue from imminent danger a case which would prove fatal under the purgative plan, and you will add greatly to your own reputation.

There is one form of this disease in which diarrhoea is a prominent symptom, where the purging is from the very commencement. On this form I am anxious that you should have clear ideas. In cases of this kind there is a copious discharge of fluid matter from the bowels. In the majority of cases, you may lay down this law, that where there is a decided irritation of any secreting organ, increased discharges from the surface of that organ give more or less relief. Suppose two cases of hepatitis; in the one we have no secretion of bile, in the other the secretion is copious; the latter is certainly most favourable. Again, suppose two cases of bronchitis; in one there is a copious expectoration, in the other it is extremely scanty; now every medical man knows that the former is more easily managed. The increased secretion of any organ in the early stage is to be looked upon as a relief to the inflammation. The practical inference to be deduced from this is, that we should be cautious in adopting any means of arresting this discharge, as it is one of the modes which nature employs in relieving the irritation of a suffering organ. Well, then, suppose you have a case of enteritis, and that on the first or second day diarrhoea sets in, what does the routine and systematic physician do? He gives chalk mixture and opium with tincture of kino and catechu, and what is the consequence? The belly becomes tympanitic; the pain is increased, and even peritonitis may supervene;—this is one result of the increase of inflammation; or the breathing becomes difficult, and the patient gets bronchitis or pneumonia. Diarrhoea occurring in the early period of this disease is not to be interfered with, except when it gets to such a height as to threaten the patient's life; and where it increases his sufferings by the frequency of the discharges. In the first week or fortnight, when there are only three or four discharges, or even five in the twenty-four hours, I believe it is better not to interfere by prescribing direct astringents; *but in the advanced period, when the powers of life are low, or the discharges very copious*, then the physician comes to the assistance of nature with just reason, and in such cases you should always interfere. The best mode of managing diarrhoea of this kind is to employ small, frequently repeated doses of Dover's powder, with anodyne injections. And here I may mention briefly, to such of you as have not seen them used, the best way of employing them. As these injections are used on a different principle from the common, the latter being intended to empty the great intestine and be discharged, the former to be retained, we are consequently to make the basis of our anodyne injection in such a manner, that it will not prove stimulant from its bulk, or from

any irritating substance it may contain. Mucilage of starch, new milk, or linseed decoction may be used as the basis, and the quantity taken for one injection should never exceed three ounces. To this, for an adult, you add from fifteen to thirty drops of tincture of opium, for it is a curious fact connected with this subject, that opium given by the rectum has frequently been observed to exercise a much more powerful effect on the system than when an equal or even smaller quantity has been taken by the mouth. The rule then is, that when you first make trial of the remedy in this manner, feel your way cautiously, and if you find that your patient bears ten or fifteen drops, you can increase the quantity on repeating the enema. An eminent practitioner of this city thinks the narcotic effect of opium by the rectum much better marked than by the mouth, and I believe this to be true in many instances. I believe the administration of opium in this way requires a good deal of caution. I recollect the case of a man who had been for a considerable length of time in the habit of using laudanum in large quantities, and was, in fact, a regular opium eater. During an attack of illness he got an injection containing sixty drops of laudanum; this produced, in a very short time, symptoms of decided narcotism, from which the patient never recovered; in fact, he died with every appearance of being poisoned by opium. There is another fact with respect to this disease, which I would have you bear in mind, that, under certain circumstances, inflammation of the small intestine will produce a remarkable tolerance of opium. This applies not only to the advanced stage of enteritis, but also to many other forms of disease. Some time since I made a series of clinical experiments with the view of ascertaining the power which opium possesses in relieving inflammation, and the result has been, that in many cases where the powers of life are so low that we cannot have recourse to the lancet, or any kind of depletory measures, opium alone furnishes us with a powerful means of subduing inflammatory action. When we come to treat of peritonitis, I shall have occasion to speak of the good effects of very large doses of opium, particularly in that form of the disease which results from intestinal perforation. My first trials of this remedy were in affections of serous membranes, and to this I was led by some interesting clinical experiments made by Dr. Graves. I next tried it in diseases of mucous membranes, where antiphlogistics were inadmissible, and here, as in the former cases, I had many proofs of its great efficacy. I shall state the particulars of a very remarkable case. A young gentleman, a pupil of mine, and a member of the class at Park-street, of an irritable habit, was attacked with intense inflammation of the mucous membrane of the intestine. He had a high degree of fever, and his thirst was so insatiable, that for two days he never ceased calling for drink. His pulse was weak

but rapid; his tongue red and pointed; respiration very much hurried; but the stethoscopic signs of disease of the lung were absent. His belly was exceedingly tender on pressure; and he had another remarkable symptom—constant smacking of the lips. The case, as you may perceive, was one of severe gastro-enteritis, and it was treated in the ordinary mode, by leeches, cold water, &c., but the disease showed great obstinacy, and at the end of a month the patient was evidently in a state of imminent danger. At this period a curious revulsion took place: the chest became engaged, and the patient got bronchitis. For this he was blistered, and took the decoct. polygalæ with large doses of carbonate of ammonia, under the use of which he recovered. The bronchitis disappeared, but was almost immediately replaced by symptoms of intense gastro-enteric inflammation, thirst, quick pulse, tympanitis, low delirium, and subsultus tendinum. In the course of two or three days diarrhoea came on, becoming more profuse as it advanced. The first day he had four discharges, the next eight, and thus it went on increasing until there was a constant discharge of thin fluid matter from the anus. The patient was quite run down, and on three different occasions his friends thought him dead. Having made an unsuccessful trial of various stimulants and astringents, I determined to try what might be expected from large doses of opium. The patient was dying, and it was necessary to do something instantly, which would be likely to arrest the diarrhoea. I ordered a grain of opium to be given every hour; on the first day he took twelve grains with apparent benefit, the next day he took six, the same quantity on the third day, and on the fourth the diarrhoea had so much diminished, and the young gentleman was so much better, that I thought it might be safely omitted. From this period my patient recovered rapidly. I would not bring forward this case in proof of the efficacy of opium if there were not many others of a similar kind; and I have no doubt that this was a cure effected by the use of opium in large doses. In the treatment of this disease by opium, there is one simple rule, by observing which you will be able to avoid all difficulties, and at the same time have a criterion to judge of the value of the opiate treatment. If the remedy produces the ordinary narcotic effects of such large doses on the system, *it will not do much good*. You begin, therefore, cautiously; and if, after the first or second dose, you find that decided narcotism is produced, or at least more than you would think the quantity given could have brought on, give it up,—it will be dangerous. But if he bears one, two, or three grains, or if, after having taken six or eight grains in the twenty-four hours, he appears to be improving, you may then persevere in the administration of opium, and it will be attended with decided advantage.

We have next to proceed to the consideration

of the pathology and treatment of diarrhoea and dysentery; I shall, however, first exhibit a few preparations illustrative of the diseases of the small intestine. Here is a preparation of the affection called *tabes mesenterica*. You see here various masses of those cheesy glands which are generally supposed to be the result of original scrofulous deposition; but if you look along the folds of the intestine, you will see a vast number of engorged lymphatics running up directly to those glands, and you will perceive that these lymphatics correspond at their commencement with ulcerative disease of the intestinal mucous surface and glands. Here is an interesting preparation, exhibiting three distinct ulcers. In one of these you see the bright vascularity and turgescence of the areola, and the ulcerative process which has just begun in the centre. Close to this is another large ulcer, which has destroyed the texture of the gut down to its serous covering, through which you perceive the light is shining. The last is an example of perforating ulcer; all the coats of the intestine have been destroyed, and on turning the preparation you see evident marks of peritoneal inflammation. This preparation also exhibits one of the modes in which an ulcerative perforation of the intestine may terminate. Sometimes, at the very moment the ulcerative process has succeeded in destroying the last coat of the intestine, inflammation of the serous membrane in the immediate vicinity takes place, a quantity of lymph is poured out, and if the matter be not in great quantity, and the hole not too large, the opening is closed up by the effused lymph, and a stop is put to farther mischief. Again, by the effusion of lymph the ulcerated portion of the intestine may form an adhesion to another sound portion, the effused lymph does not permit the passage of the contents of the intestine into the peritoneum, but does not prevent them from getting into the sound portion by a continuance of the ulcerative process, and in this way we have another termination, in the formation of a false passage. Here is a good example of disease of the cœcum, here is an example of disease of the colon, and here is another with a vast number of ulcerations. Here is an interesting specimen of disease of the large intestine. The patient to whom it belonged died of phthisis;—look at it and you will see what extensive ravages have been made by the ulcerative process.

We come now to take up the subject of disease of the large intestine, which, as I find my time nearly past, I must reserve until our next meeting. I shall then speak of dysentery and diarrhoea, and shall draw your attention to some new and curious facts respecting the discharge of fatty matter from the bowels. In the last number of the *Medico-Chirurgical Transactions*, three separate papers have appeared on this subject from Dr. Elliotson, Dr. Bright, and Mr. Lloyd. Dr. Bright has brought forward several in-

interesting facts tending to show that discharges of fatty matter may be found to be indicative of certain forms of disease of the digestive tube and the neighbouring glands.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS AND CHILDREN,

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE XIV.

Development of the Nervous, or Cerebro-spinal System, and of the Intellectual Functions in Infancy.

GENTLEMEN,—In the preceding lectures I described the physiology and hygiene of the cutaneous, digestive, nutritive, and muscular systems in the economy of infants; and it now remains for me to notice that which has long been considered the most important of all, the development of the nervous, or cerebro-spinal system, and of the intellectual functions.

It is almost universally admitted by modern physiologists, that the brain and spinal marrow are first formed in the human embryo, and next appears the *punctum saliens*, or heart. The spinal marrow and bulb of the brain are the basis of the heart and blood-vessels. The younger the ovule, or embryo, the greater in proportion is the nervous apparatus. "It is this system," says M. Virey, "that eminently constitutes the animal, and particularly man, the most sensible and *cerebral* of beings; it is the nervous system which gives motion to all the economy, even to the acephalous foetus; and the experiments of our regretted and ingenuous confrère Legallois have proved, that the action of the heart principally depends upon the influence of the spinal marrow. The new-born infant is extremely nervous, notwithstanding its soft texture, and though its external senses may be as yet inactive and imperfect, every thing is pain to this delicate and frail being, every thing violently agitates its organisation; the slightest impressions, a slight colic cause convulsions, frightful spasms, a mortal tetanus, especially in warm climates. No disease of infants is free from nervous symptoms, as the great Boerhaave remarked. The large head, the excessive irritability of fibre, the perpetual mobility of the infant, make it to pass suddenly from tears to laughter, from one affection to another; this *impressionability* very well demonstrates the prodigious dominion of the nervous apparatus in the first period of its existence. All conspire in its organisation with the most perfect energy, both in the adult and in the aged, hence that intense life, that feverish and

rapid growth, and hence the frequent want of sleep and nourishment.

"It is important, nevertheless, that it is not alone in the brain, but in the great sympathetic nerve, that the greatest infantile energy exists. The brain is almost fluid, receives slightly some fugitive impressions, it does not form as yet any thought, and if it slightly direct some volition, or some feeble muscular motions, these appear to be merely instinctive, automatic, or dependent on the sensibility of each organ. Hence the new being almost sleeps constantly, because its brain is in a state of collapse, or inactivity. But the internal functions of digestion, on the contrary, of assimilation, are extremely active, and are incessantly aroused by the latter part of the nervous system, which presides over this internal life.

"It follows from this, that the first natural impulsions of a new-born infant are not reflections, or the product of sensations acquired by the external senses, but that they emanate from instinct, that interior stimulation, which leads every being to its conservation, without the necessity of thought, will, or judgment. It is this expression of the organs, it is this voice of the body, that cries in the bowels of the infant, makes it search for the nipple, and suck it; that impels the newly yeaned lamb to recognise its mother in a large flock; it is this instinct of conformation that teaches the kid to butt with its head, as if it already had horns, or, in other words, the innate ideas of horns; it is this same instinct which directs animals to distinguish among herbs, the most wholesome for their nourishment."—Dict. des Sciences Médicales, art. ENFANS.

The new-born infant has no idea of external objects, it has no ideas, thoughts, memory, judgment, desires, or passions; its intellectual or moral life is entirely "null and void." Some writers have asserted, that about the fortieth day the infant commences to establish a correspondence between itself and surrounding objects, and that, until this age, its senses are dull, and can only exert a feeble action; but that then they awake, and become the instruments proper for sensations, and the generation of ideas. This observation is certainly incorrect, for I have repeatedly seen infants, a few minutes after birth, fix their eyes intently upon a lighted candle, or the fire, and even on the drapery of the bed, or the walls of the chamber. Ideas must therefore commence before the period just stated, and must depend upon the perfection of the development of the body and the senses. As the development of the body differs very much in different infants, it appears to me to be impossible, to fix the period at which the senses of vision, audition, olfaction, gustation, and touch are first exerted.

Sooner or later the innate power of perception is established, the understanding is developed, the will, or volition, is manifested, and reason becomes apparent at a later period.

At an undefined time the infant recognises the smiles of its mother, or, as a favourite poet of old has it,—

"Incipe, parve puer, risu cognoscere matrem."

This, then, is unquestionably, or at least perhaps, the first sign of intellect, for this smile marks the perception of what is pleasing; it is peculiar to the human species only.

According to Professor Capuron, we should commence the moral education of man when he is in his cradle, when his natural flexibility enables us to form his mind and his heart. Infancy is the age of imitation, the infant sucks with the milk, good as well as bad impressions, and the habits that it contracts, are extremely difficult to be destroyed in after life, as they are deeply rooted. The virtues and vices of man depend on the nurse, who was their first institutor.

The education of the senses is the first object which ought to occupy us, for without these, continues M. Capuron, there are no ideas, no judgment, no intellect, in a word, no man. The senses of vision, hearing, and touch are those that transmit most of the impressions of the mind. The new-born infant cannot distinguish appearances from realities. All that he sees, all that he hears are applied to the retina and the tympanum. He then employs his hand to examine all that he understands; the sense of touch gradually develops, comes to the aid of vision and hearing, it enables infants to learn the form, solidity, temperature, and dimensions of objects.

We observe the infant exerting its hands soon after birth, and at first unable to grasp or hold objects. The primary duty of the nurse, is to forewarn it against the errors and illusions of the senses. She should make it apprehend, above all things, to mistrust first impressions, and not to judge of objects until after they have been well considered; and this is the true mode to render it less presumptuous afterwards, and less subject to prejudice. The infant which is extremely delicate and mobile, or nervous, readily takes alarm, and is frightened at the slightest thing. It therefore requires the greatest possible precaution in its management.

It should be accustomed very gradually, almost insensibly, to look on various objects, to touch, and examine them. It first views them, then touches them, and, finally, is not afraid of them.

It is necessary to expose it to a proper light, as it naturally abhors darkness, and is frightened, or alarmed to tears when left in profound obscurity. It should be taught or inspired with a just regard or notion of every thing which is hurtful to it, as fire, the blaze of a candle, dangerous situations, certain articles of furniture, certain animals, &c.

At an early age, generally from the sixth to the twelfth month, the infant attempts to exert its organ of speech; it pronounces the

vowel *a*, and some of the labial consonants, which are the first that escape from the infantile lips all over the world; and the words *pa* and *ma*, or *papa* and *mamma*, are expressed in all languages. At first, all the words the infant expresses are by imitation, but it does not comprehend their meaning. The words *pa*, *da*, and *ma*, are so often repeated to it, that it soon comprehends their reference to its parents.

The faculty of imitation, which an infant possesses in an eminent degree, is one of the chief means of its instruction; in fact, it imitates and counterfeits all that it sees. It therefore follows, that the actions and expressions of those, who direct it, should be calculated to improve its mind and body.

Perception and memory are admirable with most infants, who perceive with astonishing rapidity the various objects which surround them, and the impressions made become so profound, that they often subsist or continue even to old age. But infants have not the power of comparison or judgment well developed, because these faculties require a great concurrence of ideas, to compare and examine their resemblances and differences; the infant is too delicate, too inconstant, too little susceptible of long attention and cool reflections, which are necessary for correct judgment and perfect reason. It directs its attention to physical objects, to things which act on its senses. Every thing which it sees vividly excites its curiosity. The avidity which it displays, and the velocity of its movements, excite the action of the heart and arteries, accelerate the circulation of the blood for the support of every organ, and largely conduce to the growth of the body, and the preservation of health. The vehemence of these movements rouse emotions of vivacity, gaiety, &c. The sensations are the first scintillations of the hitherto dormant mind. The most material senses have most activity in infancy, such as taste and touch. The first is apparent in the great appetite of early age, for almost all infants are gluttons; the second, or touch, gives exact ideas of all surrounding objects.

The imagination of the infant is gradually and slowly developed; and hence it cannot be delirious or maniacal, though it may be almost rendered an idiot by harsh treatment. All rude impressions and severe pains depress the nervous system (the seat of the mind), as we observe those unfortunate infants who are inhumanly subjected to severe chastisements, dejected by long-continued fears.

The infant soon distinguishes between those things that please and gratify it, and those that shock or hurt it. As a general rule, it ought to be refused every thing hurtful to it. Every thing which incommodes or displeases it ought to be avoided. This precept also holds good with respect to love and aversion, pleasure and pain, joy and sadness, and to all those movements, more or less tumultuous, which have such powerful influence on the

moral and physical states of man. The passions, in general, are only the affections of the soul, depraved or carried to excess; and hence it follows, that restraining and moderating them on their development are most essential. The mind of the infant has been compared to soft wax, which readily receives an impression, and to a twig, which readily bends when young, but resists when old. This was an ancient proverb, and beautifully expressed by one of our poets,—

“ ’Tis education makes the human mind,
Just as the twig is bent, the tree's inclined.”

Parents and others who have the management of children, should, with vigilance and without severity, fix the character and inclinations of their precious little charges, while they are young and easily managed.

“ How profitable is it,” says M. Capuron, “ to give an infant, at an early age, an agreeable physiognomy, a noble mien, to inspire it with soft prepossessing manners,—in fine, to render it gay without heedlessness, lively without petulance, an enemy to mendacity, and a friend to truth. After some years, or months, and perhaps a very short time, it will be necessary to have recourse to violence and rigour, to correct those errors which a good example would have prevented.”

From the preceding statements it appears evident, that the physical education of infants ought to commence immediately after birth, and demands great attention. The infant soon perceives surrounding objects, and the first impressions made on its temper by nurses have influence long after they are forgotten. Care should, therefore, be taken not to suffer the infant to be dull, and, after a certain age, not to exhaust its senses by constant excitement. Nature obviates fatigue by inducing rest and repose. She is so careful of the infant, that its exertions need seldom be interrupted, unless when they are likely to prove injurious. Infants should be allowed to examine all things within their reach, unless such as are dangerous, so as to enable them to acquire knowledge by their own experience. All dangerous things should be put out of reach, instead of cautioning an infant against them, for he does not know the reason of such prohibitions, and, from his curiosity, seldom obeys them.

The first words a child learns are the terms applied to parents, and then the names of things, and these are easily associated with the objects themselves. It would be foreign to my present purpose of lecturing on the physical education of children, to consider the source of simple and compound ideas, or enter on the abstruse subject of metaphysics, for we must be content, at present, with the hygiene of infancy. I may, however, observe, that an infant acquires knowledge, by its attention being directed from particular to general ideas.

The greatest caution should be observed in selecting nurses and nursery maids, as stated

in a former lecture, because the language, manners, vulgar tricks, lying, cunning, blasphemy, and obscenity, learned by children from servants, disgust and shock every well bred and enlightened individual.

It is morally impossible to depend upon the veracity of mercenary nurses or servants, in their management of, and intercourse with, children. A large sized volume might be written in illustration of the validity of this position. There is no one so competent to superintend the rearing of an infant as an affectionate and experienced mother. A woman who is a mother can alone nurse an infant properly; young and inexperienced nursery maids greatly mismanage children. A negligent, passionate servant injures the temper and health of the child, and will not take the trouble to distinguish between the roar of pain and passion; and if the nurse is ill-tempered or careless, her unfortunate foster child will be neglected, and be in a constant state of fretfulness and ill health. On the contrary, an affectionate, cheerful, and careful nurse will render the child lively and good tempered, and secure to it good health. A stupid, slovenly woman is not fit to have the care of a child. The practice of “ shaking and roaring at children ” is highly dangerous; while frightening or hurting them has frequently brought on convulsions, and often immediate death. Fears, cruelty, or chastisements, are totally unnecessary in the management of children. We should by mildness, persuasion, and promises of reward for good conduct, moderate and suppress passion, peevishness, fretfulness, vanity, pride, and ambition, and inculcate the practice of probity and virtue. It is an admirable plan to excite the emulation. We should not follow the advice of M. Rousseau to teach truth by falsehood. Honesty is the best policy in education. It is requisite to be exact in requiring obedience, or we soon cannot obtain it, either by persuasion or authority. Children should be taught to admire truth, and feel ashamed of falsehood.

The physical education of early infancy is principally conducted in the nursery, and therefore the regulation of this apartment deserves attention.

The nursery is generally situated on the upper floor in these countries; and should be perfectly dry; the windows tight, and the bed or cot situated at some distance from the door, more especially when this opens on the staircase, so as to prevent the bad effects of cold draughts. There should be a lattice door at the head of the stairs, with the laths placed perpendicular or across each other, so that the child cannot climb upon them. The windows should have cross-bars about five inches from each other, and shutters, so as to darken the apartment when it is necessary to exclude the light. When there is an open stove or fire, it should be surrounded with a high wire fender; and this is preferable to a close stove, which often

inflicts severe burns. If a lamp or candle be used at night, which is seldom necessary, it should be placed near the stove or fire-place, so that the smoke may escape, for were this to mix with the air of the chamber, it would be very prejudicial to respiration. The floor should be carpeted, especially in cold weather, and the carpet should be shaken at least once a week to free it from dust, which would be raised in the air by exercise, and excite irritation in the throat, or coughing.

The principal furniture of a nursery consists of a bed, cot, a few chairs, and a table, with fire-irons, and basin stand. Mattresses are preferable to feather beds, which are much too warm for children, cause disturbed sleep, profuse perspiration, and relaxation of the whole body. Children should sleep in separate beds when practicable, and have sufficient, but not too much bed clothes. I have already mentioned the importance of putting children to bed at an early hour, at seven or eight o'clock, as they generally awake at daylight, and the nurse should be by the bed by day.

It is a bad practice to allow the child to take much fluid or drink before bed hour, as this leads to the inconvenient habit of wetting the bed. This habit is caused by the excessive irritability of the bladder in some children, and it is cruel to punish them for it. The best mode of preventing it is, to diminish the quantity of drink of an evening, and to administer a proper dose of laudanum, according to the age and strength of the child. I have repeatedly prevented this habit in children from the age of five to eleven years, by this plan of treatment.

The nursery should be properly ventilated every day, and the floor kept dry, and the ordinary domestic pursuits, as washing, ironing, &c., expose the child to danger, and consequently should not be performed in it.

This apartment should never contain any furniture that the child could spoil, or hurt itself with; it ought to be provided with the means of amusement, as pieces of wood of various sizes, to build up and pull down houses, castles, &c., wheels, carts to carry playthings, "backgammon tables, battledore and shuttlecock, a rocking-horse, slates, pencils, dissected maps, &c., &c." (Dewees); things which excite children to exert their own powers of imitation. Many eminent writers have recommended toys and playthings (Edgeworth, Dewees, &c.), while M. Rousseau wrote an express chapter on dolls.

All sharp-pointed instruments, pieces of stick, swords, &c., should be excluded, as wounds have been inflicted by these on children, which caused tetanus, convulsions, and blindness of both eyes. It is also important to caution children against running on the floor without shoes, as they may tread on pins, needles, nails, &c.; and against falling on their playthings. There is an old prejudice that dogs, but especially cats, should be excluded from the nursery, as they are supposed to

"suck the child's breath," or in other words to stop its respiration, and cause suffocation. There is no truth in this opinion; but if a cat or dog lay on the chest or abdomen of the infant, respiration might be so much impeded as to induce congestion of the brain, and suffocation.

A child breaks his playthings, not from love of mischief, but from a hatred of idleness; he wishes to see what these are made of, and how they are made, and whether he can put them together after he has separated their parts. All this curiosity is perfectly innocent, and it is a pity that his love of knowledge and spirit of activity, should be repressed by reprehension or correction. An infant is impelled by that desire of novelty, inherent in our nature. It was observed from an early age,—

"Natura hominum, novitatis avida."

Children ought to have toys on which they can exercise their senses or their imagination, their imitative or inventive powers. It is wrong to lecture a child for having broken his toys, until, as Miss Edgeworth graphically observes, in her *Practical Education*, "the contrite corners of his mouth are drawn down, his wide eyes filled with tears, and without knowing what he means, promises never to be so silly any more. The future safety of his worthless playthings is thus purchased at the expense of his understanding, perhaps of his infant integrity, for children seldom scrupulously adhere to promises which they have made to escape impending punishment."

It is scarcely necessary to mention, that all small toys, pieces of money, or such things as might be swallowed, should be withheld from children.

Such are the principal precepts with respect to the furniture and management of the nursery.

It is to be recollected, that young children are not endowed with perfect reason, and are solely guided by instinct; and that, if they do wrong, it is without reflection, and by the impulse of desire. It is therefore manifest, that they are not responsible beings, and consequently it is cruel to inflict corporal punishments upon them for their inevitable errors. They are most properly held irresponsible by law, and by all enlightened individuals. I cannot agree with some philosophers, who argue against this conclusion, that as many of the inferior animals, dogs, monkeys, cats, &c., punish their young, so should parents. In answer, it may be urged, that these animals are not endowed with reason.

When we consider the delicacy of the infantile body and constitution, we cannot but be shocked on seeing severe blows inflicted on the infantile head, a part so liable to fatal diseases; and on different other parts, all easily injured. Every feeling of humanity is roused, on witnessing the barbarous brutality of some parents and pedagogues towards defenceless children; and every medical practitioner must shudder at the fatal results.

Corporal chastisements, say moralists, degrade the character, render the infant timid, dull, servile, and incapable of courage and of virtue; so that it refrains from bad conduct on account of fear only, and will commit errors as often as it hopes to escape with impunity.

It is the opinion of M. Virey, and almost all who have written on the physical education of children, that corporal chastisements may be almost entirely dispensed with.

The worst consequences will be induced when infants are constantly crying, such as rupture, cough, inflammation of the lungs and brain, water in the head, general debility, emaciation or wasting of the body. Those who have the care of infants should pacify them when out of temper by walking, motion, and fixing their attention on such objects as please them. It is cruel and barbarous to scold, threaten, violently shake, or beat them.

They should be pleased and gratified, their attempts to speak, their little cooing or "crowing" songs encouraged, and every effort employed to keep them in good humour. When properly managed, remonstrance or correction is seldom necessary. Children should be ruled by love, affection, and kindness, and not by harshness or insensibility. But too much indulgence is injudicious. Irritation or anger should be suppressed by mildness and benevolence. Love, affection, patience, and mildness are the only rational means of managing and correcting the errors or faults of children.

The mode of educating children, so soon as they have sufficient reason, which is generally adopted and recommended by the members of our profession, is to impress and encourage self-love and emulation, which nature has implanted in all our species. They should be taught to love their parents, nurses, and each other; applauded for their good, and reproved for their bad actions; and clearly shown the impropriety of the latter. They should be informed of the difference between justice and injustice, weakness and strength, and the rights of each other. They ought to comprehend from the cradle, what is right and good, as well as justice, paternal authority, the nature of an equitable rule of conduct, their duties to all, and most particularly to their Creator.

The management or education of the intellectual faculties belongs to the domains of medicine and metaphysics. Two points on this important subject deserve attention. The first, that man is naturally averse to labour, unless its object be pleasure or desire; and the second, that it is as extremely injurious to excite the brain by premature study, as it is the muscles by premature exercise. It is indispensable to health and a good constitution, that children of a tender age should be properly managed with respect to diet, clothing, exercise in the open air, and repose; because, without due attention to these requisites, neither mind nor body will be properly developed.

MR. SALMON'S REPLY TO DR. O'BEIRNE.

PATHOLOGY AND DISEASES OF THE RECTUM.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—My observations on Dr. O'Beirne's last letter shall be as brief as his accusations and numerous misstatements will permit. He commences—"Mr. Salmon's reply is a general one, embracing a variety of points, calculated to divert the mind from the subject of organic stricture, upon which we are mainly at issue, and which we had mutually agreed to leave to the decision of two distinguished members of the profession;" thus insinuating that I had introduced new matter for controversy. Now a reference to my letter of November the 30th will prove that I confined my answer to such points only as Dr. O'Beirne had advanced; my reply therefore was not a general one in the sense he implies, though it was a general, and, I think I may add, from the discomfiture he manifests, a satisfactory one to all his positions.

I will endeavour to make my present letter alike conclusive to all unprejudiced persons. *Imprimis*, I must express my regret that he has again compelled me to exculpate myself from charges conveyed in so sophistical a manner, that they carry with them the appearance of truth, though, as I shall presently show, they possess not the smallest portion of that inestimable principle. I am accused of a "*positive breach of contract*;" a simple narrative of facts will convey a full and unequivocal refutation of this accusation. In my letter, published in your Journal of the 20th April, I undertook to prove, by preparations in my possession, the existence of "permanent stricture in the lower part of the rectum," and offered to show those to any members of our profession. Dr. O'Beirne in substance answered, that if either of his friends, Mr. Guthrie or Mr. Bransby Cooper, would confirm what I had said, he would believe it, retract his opinions, and admit, what he has in his last letter again denied, the existence of that disease. Considering the point was of importance to science, I complied with Dr. O'Beirne's challenge, and, as I before stated, immediately wrote to Mr. Cooper; I however thought proper to ask Dr. Blundell to meet him. Both of these gentlemen politely acceded to my request, and an appointment was made to inspect the preparations. Dr. Blundell and Mr. Cooper did not, however, meet, at least not with my knowledge, the former gentlemen being behind his appointment. I had selected for their inspection fifteen preparations of stricture of the rectum only. Mr. Cooper took a cursory view of those, and left, saying, he supposed he should see or hear from Dr. Blundell. Upon this

gentleman's arrival, he also inspected the preparations, and desired certain ones which he selected to be sent to his residence. I heard nothing more, directly or indirectly, of Mr. Cooper, till I wrote to him for his opinion a day or two before the date of the first of his letters herewith published; neither did I hear from Dr. Blundell till the day before I wrote my reply to Mr. Oldknow, which appeared in the *Lancet* of November the 16th, when I read a rough copy of what Dr. Blundell had formed as his opinion. His final judgment I only received, as our letters show, on the 30th November. From these facts it is clear that Dr. O'Beirne and I never "*mutually agreed to leave the matter to the decision*" of Dr. Blundell and Mr. Cooper, for the former gentleman was not mentioned; nor would he have ever been heard of in the affair till the publication of my last letter, had not Dr. O'Beirne been apprized of his having inspected the specimens by Mr. Cooper. I further "*submit to the profession,*" that had I chosen to obtain the opinion of fifty individuals upon the character of the preparations, I was at perfect liberty to do so; neither could such a course injure Dr. O'Beirne, as those persons could only testify from ocular demonstration of a matter of fact, the confirmation or refutation of which ought to be his first consideration. He complains of the time which elapsed before the decision was made public. Now for such delay I apologise, stating "the truth is, I have not had the documents necessary to complete the answer till very lately, (which fact a reference to the accompanying correspondence confirms,) added to which, my leisure has been completely occupied by the affairs relative to my resignation at the General Dispensary." After that explanation, it was anything but kind in Dr. O'Beirne to state that there was a "hitch somewhere." He proceeds—"I had the favourable documents (Dr. Blundell's and Mr. Cooper's decisions) so early as the middle of November;" but he was too scrupulous, it appears, to expose my ignorance, by giving them publicity. Favourable, however, as he would lead us to suppose he thought them, we nevertheless find him writing to Mr. Cooper, and suggesting the "*necessity of slitting the preparations marked A and B their whole length, before either he or Dr. Blundell could come to a FINAL decision.*" But it would (not it does) appear that Mr. Cooper was "prevented from making this fair and considerate proposal by a step which Mr. Salmon had taken in the mean time, namely, requesting Mr. Stanley and Dr. Ryan to inspect his preparations." The extreme modesty of Dr. O'Beirne's proposition every Curator of Anatomical Preparations will fully appreciate; and it was no wonder that a gentleman, of the correct feeling Mr. Bransby Cooper is known to possess, abstained from making it. Unfortunately, however, for the Doctor, it so happens that the preparations have been slit open,

so as to exhibit their diseased condition, ever since they were put up; nevertheless, the reason assigned by him why they were not so mutilated is contradicted by Mr. Cooper's correspondence, which clearly proves, that the final decision of Dr. Blundell and the former gentlemen were in Dr. O'Beirne's possession many, many days before his destructive proposition was requested to be made. From the manner in which he speaks of the reason I assigned for requesting Mr. Stanley and Dr. Ryan's judgment, your readers would gather that I meant the words "finding they disagreed so materially" to apply to some matter of conversation between Dr. Blundell and Mr. Cooper, though Dr. O'Beirne must have known that the words were used in reference to their recorded opinions, as my letters to the latter of these two gentlemen likewise illustrate; and as to Dr. O'Beirne's assertion, that those documents "*perfectly agree, the merest tyro in the profession* (to repeat his classical and elegant language) *has only to compare both in order to be convinced that they are as widely different as light from darkness.*" I should forget the respect due to myself and your readers, even more than my opponent has done, were I to notice the paragraph wherein he charges me with not "*being over squeamish or punctilious in availing myself of advantages,*" which exist only in his imagination.

He next proceeds to illustrate "*the exact nature and practical bearing*" of our controversy, which of course no one, "*except his friend, Mr. Cooper,*" has fully understood; and to explain his own peculiar views, so as to "*succeed in placing the whole subject in a clearer, fuller, and much more useful points of view, than the plan*" of his work "*admitted.*" Here we have a clear admission that his book, published for the avowed purpose of proving and promulgating his "*new views,*" is so unsatisfactory, even to its author, that he feels it necessary to illustrate his ideas on one of its most important points, by an explanatory letter to a weekly periodical. In furtherance of this illustration, he gives "*the received ideas of the morbid conditions constituting organic and permanent stricture;*" not, however, by quoting my opinion on the subject, but those "*of the latest writer.*" Here I forbear making any further remark, except that I account it both uncourteous and unfair to condemn or detract from the opinions of any individual, either publicly or in private, with whom I am not controversially engaged. Had Dr. O'Beirne extracted the morbid anatomy of the rectum from my work, the originality of his notions would have vanished into thin air; for he must have shown that I speak of circumscribed, partial and general thickening of the rectum, yet remark upon the healthy condition of its mucous tunic, in contra-distinction to all authors who had preceded me. Dr. O'Beirne next misapplies my words, making it appear that I disavowed the

existence of permanent stricture any where *but* in the lower part of the bowel. Now he must have been aware, that the words he has quoted were used in reply to *his* denying the existence of permanent contraction below the union of the colon and rectum, "a latitude of opinion," which, to use my former language, even "I had not given Dr. O'Beirne credit for, since I merely contended" (that is in my controversy with him) "for permanent stricture in the lower part of the rectum."

He proceeds to say, that Mr. Salmon admits "*that distinct thickened and shelf-like projections are exceedingly unusual in the two upper thirds of the rectum.*" Now I did not admit any such thing, but I did infer it, and I now maintain that such is the fact, because, as I before said, "a uniform thickening," but not shelf-like projections, is the common morbid appearances of stricture in the two upper thirds of the bowel. Dr. O'Beirne's reasoning against circular stricture, resulting from a redundancy of the circular fibres, is singularly scientific, since from it we are to infer, that because the action of the circular and longitudinal fibres is "*simultaneous relaxation and contraction,*" the preponderating power of the former set of fibres is of no avail; and this too is asserted in the face of his own friend's decision, who says "the specimen of distinct thread-like construction, which I saw producing the distinct circular contraction" was "spasmodic." Now, is it not clear, if such an effect can be produced from spasm, this, or the causes which gave rise to it, continuing, the contraction would become permanent. Dr. O'Beirne asks "*are the statements just referred to sustained by the evidence of pathological anatomy,*" and, in proof that such is not the case, writes "*I shall now state both the morbid changes I have not observed, and those which I have observed, except AT THE UPPER EXTREMITY I observed no partial thickening of the parietes of the intestines.*" Yet a little further on we find him admitting, as appearances which he has observed, "*all that great portion of the rectum above its pouch thickened in its parietes and contracted in its cavity.*" Thus have his researches into the morbid anatomy of the rectum led him not only to contradict himself, but also fully to confirm my published opinions on that subject.

We are next favoured with a lengthened dissertation upon his "*new views,*" the "*practical bearing*" of which he proceeds to show, also to prove the "*unscientific and dangerous nature of a practice evidently suggested by the erroneous notion of stricture,*" to wit, the division of the disease when situated near to the anus, an operation which he is kind enough to say is "*recommended,*" among others, by "*Mr. Salmon.*" A short extract from the chapter in my work, which treats of the division of stricture, will show how carefully he has perused, and how clearly he has comprehended, my observations on this sub-

ject:—"Taking into consideration the danger consequent upon hæmorrhage, the probability of inflammation, and the distressing irritation which arises from the necessity of keeping the divided portions of the gut separated during the healing process, the division of a stricture may always be accounted a dangerous, and, in many cases, an equally useless operation. There are few instances where it can be attempted consistently with utility and safety." I then assign my reasons why I would not perform the operation, and direct "the reader's attention to the distinction between that kind of obstruction which is produced from the formation of adventitious bands or septa in the rectum, and stricture of the gut itself," the former of which, I state, "may be freely divided without any apprehension of danger." Having described the manner of performing the operation, I terminate my remarks by stating that "upon the whole the operation is not of a description to induce me to recommend its performance, such at least is the result of my experience; under the most favourable issue, I do not think it likely to be productive of that degree of success, which may be considered a compensation for so hazardous and painful an expedient *."

Few of your readers would, I should suppose, be deceived by the plausible manner in which Dr. O'Beirne makes it appear that because I deny "*shelf-like projections*" as a common appearance in the "*two upper thirds of the rectum,*" that I deny the existence of stricture at those parts. Quite the contrary, as the sense of my writings, unperturbed, demonstrates; wherein I say, that "the most common situation of contraction, in such cases as have fallen under my observation, is between five and six inches from the anus." Next in frequency I have discovered the disease at the junction of the rectum with the colon; but the appearance of these obstructions will not be shelf-like projections (except at the angles of the bowel), but one uniform thickening of its parietes.

Although I am satisfied no one who is acquainted with the morbid anatomy of the rectum is likely to be led away by Dr. O'Beirne's argumentative attempts to prove the concordance of Mr. Cooper's judgment with that of Drs. Blundell and Ryan, and Mr. Stanley, I must not omit showing the clever manner in which he "*most gratuitously*" attempts to maintain this position, by ascribing to me opinions I have never entertained. He asks, "*are such appearances on the external surface of the bowel the natural consequence of organic stricture?*" (alluding to the remarks of Drs. Blundell, Ryan, and Mr. Stanley.) My reply is, yes; and further, there are proofs of the fact. The Doctor says "no." "*Even my opponent admits that this form of the disease is produced*"

* Salmon on the Rectum. Fourth edition, page 86.

by the deposition of new matter between the mucous and muscular coats, and that this new matter, instead of approximating, separates these coats from each other, and consequently opposes the formation of anything like an indentation on the external surface of the gut."

Now what do I really say upon circular stricture of the rectum, within reach of the finger, the point upon which we are here at issue?

"We sometimes find bands of a firm consistence extending from side to side, forming septa across the bowel; these septa are most commonly situated toward the inferior part of the gut. Then again we find the intestine contracted in a circular form, being dilated, immediately above the contracted part, by the perpetual lodgment of fæces, in the form of an hour-glass. This is by far the most formidable kind of simple contraction, as well as the most difficult of alleviation. But the peculiar and morbid change, generally found in cases of confirmed stricture, appears to be the result of considerable thickening of the bowel, from deposition in the cellular tissue which connects the muscular and mucous coats *."

I will not comment any further upon these "similar" opinions than to add, that Dr. O'Beirne has a happy knack of noticing what may by possibility be distorted in his favour, and of carefully avoiding what satisfactorily refutes his positions. Thus we find that of Mr. Cooper's decision of the spasmodic annular stricture (fully proved by Drs. Blundell and Ryan, and Mr. Stanley, to be a case of permanent obstruction) he says "*Mr. Cooper, in a letter to me, states that the contraction is evidently not the change of structure.*" What, I would ask, have your readers to do with Mr. Cooper's private correspondence with Dr. O'Beirne; it is the former gentleman's recorded opinion they are to be guided by. Then again he says, "*Mr. Stanley, under the head of second specimen, from a male, is less accurate in his account of this preparation,*" thus taking for granted that it was the same Dr. Blundell described under Preparation B, which it was not, but a second case of circular stricture within reach of the finger; had Dr. O'Beirne read the description with the slightest attention, he must have seen this. He likewise carefully avoid alluding to the conclusion of Dr. Ryan's judgment. "From these and the other preparations, I am perfectly convinced of the existence of stricture in every part of the rectum." So also of Mr. Stanley's judgment of the 3rd case. He assumes it to have been one of thickening from fistulæ; unfortunately, however, I can attest to the contrary, having attended the patient, from whom the preparation was taken, nearly two years before any fistulæ occurred, with circular stricture, which disease I have reason to suppose was produced from the extreme cold to which he was subjected while with the expedition to

the North Pole, of which expedition he was one of the officers.

I have thus, I believe, exposed the fallacy of Dr. O'Beirne's arguments, shown the untenability of his positions, as well as, I trust, satisfactorily refuted his accusations; the performance of this disagreeable task has caused me some pain, but the personalities, to which my opponent descended, left me no alternative, and I have endeavoured "*to perform it in as respectful and moderate a manner as the circumstances will permit.*" And now, convinced that your readers, like myself, must be pretty well tired of this controversy, I beg leave to decline extending it under *any circumstances whatsoever*. Gratefully thanking you for the space you have accorded me in the pages of your valuable Journal,

I remain, Gentlemen,

Your very obedient servant,

FREDERICK SALMON.

12, Old Broad-street,
Feb. 6th, 1834.

CORRESPONDENCE,

Between Mr. Bransby B. Cooper and Mr. Salmon.

No. I.

MY DEAR SIR,—I waited for Dr. Blundell's account of your preparations until I was tired, and as I did not like to keep Dr. O'Beirne so long in suspense, I wrote him my opinion of your preparations which I saw, and have since sent him the paper Dr. Blundell enclosed to me. I kept no copy of my own opinions, respecting how far I considered your preparations held out, or rather demonstrated, your views of stricture of the rectum, but I know that it went against yours, and in favour of Dr. O'Beirne's ideas upon the subject; but I will write to O'Beirne immediately, that I may forward to you my precise words, as written under the first impression, or, if the delay be inconvenient to you, I will write the substance again.

Yours very truly,

BRANSBY B. COOPER.

[No day or date, but received Nov. 20, 1833.
F. S.]

No. II.

12, Old Broad-street, Nov. 20th, 1833.

MY DEAR SIR,—I regret that you should have sent your decision to Dr. O'Beirne without my knowledge, and confess I think that, in a question so deeply involving the interests of the community, our profession, and my character, you ought not to have done so without first apprising me of your intention. Neither does it appear to me that the reason you assign for having written to your friend, to wit, Dr. Blundell's delay, alters the circumstances of the case, since, had you communicated with me, such delay would have been satisfactorily accounted for.

This proceeding is, however, of minor im-

* Salmon on the Rectum. Fourth edition, page 22.

portance compared with the decision you state you have given upon the various preparations of stricture of the rectum submitted to your inspection, and which I must now, in justice to myself, lay before two or three other experienced morbid anatomists, notwithstanding the clear, decisive, and uncontrovertible statement Dr. Blundell forwarded to you of them, and which fully illustrates the fact I publicly pledged myself to confirm. Meanwhile, oblige me by immediately writing to Dr. O'Beirne for a copy of your opinion, with the view of my giving it publicity, in conjunction with that of Dr. Blundell, and those of others whom I may hereafter request to inspect the preparations. Apologising for giving you so much trouble, I am, dear sir,

Yours faithfully,

FRED. SALMON.

Bransby B. Cooper, Esq.

No. III.

MY DEAR SIR,—As it was impossible that you and Dr. O'Beirne could simultaneously receive the opinion I had formed of your preparations, in reference to the point in dispute between you, I cannot see why he had not the same right to have it first as you seem to claim to yourself.

Yours truly,

BRANSBY B. COOPER.

[No day or date, but received Nov. 22, 1833.—F. S.]

No. IV.

MY DEAR SIR,—Being pressed for my reply to Dr. O'Beirne, I cannot any longer delay it for the purpose of adding, as I could have wished, the opinion, which, you stated in your first note to me, you had forwarded to that gentleman, and which I rather expected would have arrived from Dublin ere this. I must therefore, in justice to Dr. O'Beirne, publish our correspondence as illustrative of your decision.

You appear to have mistaken the sense of my last letter; I only meant that I thought a copy of your opinion should have been forwarded to me as well as to Dr. O'Beirne. This, however, as it seems, could not be done, since you omitted to take a copy of it.

I am, dear sir,

Yours very faithfully,

FRED. SALMON.

12, Old Broad-street, Nov. 30th, 1833.

Bransby B. Cooper, Esq.

No. V.

MY DEAR SIR,—On inclosing you this opinion on the subject of your controversy with Dr. O'Beirne, I must leave it to yourselves to place the issue before the profession; and, believe me, that, in giving my opinion, I am actuated only by a desire to elicit truth.

I have to apologise for not having sent this to you earlier, but I have wished to have met Dr. Blundell at your house, and have taken

the preparations out of the bottles to examine them more closely. I do not, however, like to withhold my decision longer, although I should still wish to meet Dr. Blundell with you.

Yours very truly,

BRANSBY B. COOPER.

New-street, Sunday,
[Dec. 1, added by F. S.]

No. VI.

MY DEAR SIR,—I have this moment, while at dinner, received your letter, inclosing an opinion respecting the preparations. I am unable to say any more, as your servant is waiting, than that I have sent my answer to Dr. O'Beirne, to the *Medical Journal*, also a letter to you, last night, which fully explains why I did so. Am I to understand that the opinion I now receive is the copy of what you sent to Dublin to Dr. O'Beirne? Be so good as to reply to this question; also, say whether you wish the communication I have just received forwarded to the medical periodicals, in which my reply to your friend is to appear. I think if I send it before Tuesday morning it may be added.

Yours very truly,

FRED. SALMON.

Sunday, Dec. 1, quarter past 6.

No. VII.

MY DEAR SIR,—With respect to my opinion of your preparations, which I have sent to you, you are at liberty to do with it as you please. It is what I wrote immediately upon seeing your collection, and you would have had it long since had not Dr. Blundell been so tedious in his delay. I therefore sent it to Dr. O'Beirne, and now to you, as it was first written.

Why you should write a letter to me through the public journals, when there is a twopenny post, is best known to yourself.

I am, yours truly,

BRANSBY B. COOPER.

New-street, Monday morning.

No. VIII.

MY DEAR SIR,—I suppose you could not have received my note posted on Saturday night when you forwarded yours to me of this morning, or, if you had, you have again sadly misunderstood the sense of it. I have addressed no letter to you through the press; all I have done is, to forward our correspondence, relative to your judgment of the preparations, as a matter of satisfaction to Dr. O'Beirne, and the profession, an omission of which would have rendered my answer to that gentleman incomplete. I will send and stop (if possible) the publication of your correspondence; also request that the opinion I yesterday received from you may be inserted in its stead.

I am, my dear Sir, with good feeling,

Yours, very truly,

Dec. 2nd, 1833.

FRED. SALMON.

Bransby B. Cooper, Esq.

No. IX.

MY DEAR SIR,—I am sorry to be under the necessity of publishing the correspondence which passed between us relative to my controversy with Dr. O'Beirne, but the accusations he has thought proper to make affecting my character, not only for consistency but even common propriety towards you and himself, have, in my judgment, as well as in that of my friends, rendered this step absolutely necessary. I am the more surprised at the course Dr. O'Beirne has taken, since he implicates you by stating, that he had the "favourable documents," containing the opinions of yourself and Dr. Blundell, "so early as the middle of last November;" but that instead of "taking any advantage of Mr. Salmon," he (Dr. O'Beirne) wrote to Mr. Cooper, "and submitted to him the necessity of slitting the preparations marked A and B their whole length, before either he or Dr. Blundell could fairly come to a final decision." Dr. O'Beirne then adds, "that it would appear that Mr. Cooper was prevented from making this fair and considerate proposal, or interfering further in the affair, by the step Mr. Salmon had taken in the meantime—namely, requesting Mr. Stanley and Dr. Ryan to inspect his preparations, and give their opinion on the contested points." Now, the fact is, as you, I feel assured, will readily admit, that your's as well as Dr. Blundell's opinion were formed and forwarded to Dr. O'Beirne some days before I wrote to you, stating that I should request the judgment of some other individuals, which step I took, as our letters prove, because you were unable to forward me your decision on the preparations, having taken no copy of what you had sent to Dr. O'Beirne, but which you added was in his favour.

You will likewise remember that our correspondence was gone to the printers, with my answer to your friend, when the copy of your judgment, which you had sent for to Dublin, reached me, and that I stopped the press to alter my manuscript, so as to make it consistent with that judgment, and to substitute it for your letters.

Be so good as to give me a few lines in reply, stating whether the foregoing is not a correct representation of the facts of the case, which if you would do, at your earliest convenience, I shall be obliged, so that I may be enabled to give your reply publicity in the Journal of Saturday next.

In conclusion, I repeat my unfeigned regret for the course Dr. O'Beirne has compelled me to pursue, and I beg to assure you of the sincere respect and esteem of

Yours very faithfully,
FRED. SALMON.

Feb. 4th, 1834.

Bransby B. Cooper, Esq.

No. X.

MY DEAR SIR,—If you think it necessary, you are perfectly welcome to publish the correspondence between us, relative to the controversy between yourself and Dr. O'Beirne.

Yours, truly,

BRANSBY B. COOPER.

2, New-street, Feb. 5th, 1834.

Frederick Salmon, Esq.

Mr. Salmon to Dr. Blundell.

MY DEAR SIR,—I request you will be so good as to give the bearer (if it is ready), or if not, send me, by Monday morning's first post, your opinion on the preparations. I am to send it to the printers by ten o'clock on that day. Mr. Bransby Cooper has sent the one you wrote for him away to Dr. O'Beirne, so that I have no means of saving you this additional trouble.

I am, my dear Sir,
Yours, &c.

12, Old Broad-street, FRED. SALMON.
Nov. 30th, 1833.

Dr. Blundell in reply.

MY DEAR SALMON,—Excuse haste, J. B.
[Opinion returned in my note.—F. S.]

[Having thus, in justice to Mr. Salmon, inserted the foregoing documents, we must decline publishing any further communications on a subject, the bearings of which, however interesting it may be, our readers must, we feel assured, ere this be fully acquainted with. We entertain the most sincere respect for both parties, yet we are constrained to admit that, in our opinion, the Doctor is no match for his opponent; who has not only ably proved his original position, but evinced, by his clear and concise letters, a practical knowledge of the matters which originated or have emanated from this controversy.—Eds.]

STRICTURE OF THE RECTUM.

To the Editors of the London Medical and Surgical Journal.

[Press of matter excluded this communication in our last.—Eds.]

GENTLEMEN,—I have read in the pages of your Journal the controversy between Mr. Salmon and Dr. O'Beirne, wherein the latter gentleman unequivocally denies the existence of a circular stricture of the rectum within reach of the finger. As the subject is highly interesting, and most important to medical men, I am induced to trouble you with the particulars of a case, at the present time under my care, corresponding precisely to the views entertained by Mr. Salmon, and, as it bears

upon the point in dispute, you will perhaps give it insertion in your Journal. First let me refer to a passage in your publication of the 1st of February, wherein he writes:—
 “A surgeon, upon examining the rectum per anum, feels that the pouch of the intestine is so open that he can roll his finger freely about in it, and that, on pushing his finger higher up in the direction of the bowel, its point enters a narrow opening or ring. But what idea does he form of the nature of the ring? The most natural that can be; that it is formed by an opening in the centre of a septum thrown across the cavity of a gut, which he supposes to be always in a dilated and open state.”

Now, this description does not correspond with the case under my care, for, upon passing the finger about two inches up the rectum, its further passage is obstructed by a distinct hard ring, the opening through which *was* so small as not to admit the passing of a middling size glyster pipe without the greatest difficulty, and if any force were employed it gave rise to severe pain. Can this be an opening in the centre of a septum, thrown across the cavity of a gut? A gentleman, about 18 months ago, began to complain of pain in the rectum upon passing his motions, continuing for a short time after each evacuation; the bowels were acted upon from three to six times in the 24 hours; the motions were loose and occasionally tinged with blood; a continual oozing from the anus of bloody mucus, yet the general health good.

About nine months back the pain, in passing the motions, became very acute; the bowels were moved six or eight times a-day, the faeces passing with difficulty; a continual bloody purulent discharge from the anus; and the general health become very much impaired. Mr. Salmon's opinion upon the case was requested, who, after a careful examination, pronounced it to be circular stricture of the rectum, within reach of the finger, with ulceration of the mucous membrane immediately above the contraction. My patient was called into the country, which prevented his following the plan of treatment advised, and the disease continued to make a gradual but destructive progress. In November last he was unable to leave his bed, the bowels being acted upon from 20 to 30 times a-day; he also felt a constant inclination to evacuate them, and the discharge of matter from the

anus increased; the situation of my patient at this time was most deplorable. A most distinguished surgeon now saw the case, whose opinion was, that there was a distinct hardened ring about two inches from the anus, not admitting the end of the finger. This gentleman was not decided as to the stricture being of a scirrhus nature, but he yet thought it was a hopeless case. Soon afterwards Mr. Salmon, having accidentally heard that my patient was in a hopeless condition, with a zeal highly creditable, expressed a desire to examine the rectum again, as he was satisfied there was simple circular stricture of the rectum within reach of the finger, and suggested a plan of treatment, consisting of alteratives, narcotics to the rectum, and dilatation of the stricture; the result has been most satisfactory, the health is improving; the bowels are not acted upon more than four or five times a-day; the stricture has become so far dilated as to admit my passing the rectum plug No. 5 without much pain, or difficulty, though to do this eight weeks back would have been impossible, for the aperture would barely admit the plug No. 1, added to which the pain in attempting was acute in the extreme. By inserting these simple facts you will do an act of justice to the profession, and oblige your constant reader,

SAMUEL BACON.

February 10th, 1834.

CURIOUS INQUIRY ON FETICIDE.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—It is from the conviction that the objects of your Journal are the investigation of facts, and the advancement of the views of science, that I presume to trespass upon your columns.

The importance which the practice of medicine attaches to a knowledge of jurisprudence, and the responsibility conferred upon medical men by the laws of the country, in deciding, by their evidence and views, on the legal guilt or innocence of persons charged with the crime of human destruction, urges us to use all means for acquiring every particle of information, which relates to the death or corporal injury of any individual being.

The subject, which I wish to offer to the

consideration of pathologists, I beg to point out in two propositions, the validity of the one depending upon that of the other. First, Is it possible for electrical (or galvanic) influence to be transmitted through the body of a pregnant woman, which shall be destructive to the vitality of the *fœtus* and not of the *mother*? Secondly, If this be correct, can the *quantity* or *intensity* of the influence be so modified, that repeated experiments shall furnish correct data, indicative of the quantity which shall always insure the success of the operation?

That certain electrical discharges will destroy any animal of any known description or size is beyond doubt.

That shocks of the same influence will kill *small*, and yet are not sufficiently powerful to kill *large* animals, is also true, as proved by the experiments of Aldini and a host of others.

That many medicinal agents are used to procure abortion, which destroy the child and are not permanently injurious to the mother, is also a fact, which materially proves that the *fœtus* does not possess the same degree of vital tenacity as the mother. Also, that the *foetal* vitality, though blended with, and dependent upon, maternal life, can be separated by *medicinal* means, as by powerful poisonous agents; by *mechanical* means, as by the knife, stopping the circulation, or by a blow in the hysteric region; and, in all probability, by *chemical*, including electricity and galvanism.

These form important points of consideration, as connected with forensic-medical investigation, inasmuch as it may, in the hands of some, be used as an engine of destruction to the life of the *fœtus* in utero, by such females as usually find it most politic to conceal their "little errors," which are sources of painful reminiscence and lasting disgrace.

Should any of your readers be able to prove the fact by experiment on animals, and be able to delineate the diagnostic and pathological phenomena, I think a hiatus would be removed, which would considerably tend to the advantage of science.

I have the honour to subscribe myself

Yours, obediently,

A MEMBER OF THE LONDON
MEDICAL ASSOCIATION.

Saturday, February 15th, 1834.

DR. COPLAND in the Chair.

Organic Diseases of the Stomach—Dyspepsia —Gastritis.

THE usual business having been transacted,

Mr. Parkins read a paper on organic diseases of the stomach, to which, he said, that during the last few years much attention had been directed; and that consequently many new facts connected with them had been elicited. Inflammation of this organ was seldom acute, unless when the consequence of the exhibition of poison; but it was in ordinary cases found principally to exist in the chronic stage, and to give origin to those forms which are termed organic diseases. He then referred particularly to tubercles of the pylorus, and ulceration of the coats of the stomach, and entered into the symptoms, which were, however, often found to vary; when the tuberculated state was situated near the pylorus, he had found that the pain was generally referred to the right hypochondrium, but the symptoms were so similar in many of these diseases, that no criterion could be formed from any one. The testimonies of Dr. Andral and Dr. Abercrombie were adduced in confirmation of the opinions of the author, and a case was related which showed that ulcers might exist without causing any of the usual symptoms, and that the greatest alteration of texture might take place without affording any diagnosis to the observer by which he might suspect the existence of such alteration; the causes of death in such diseases were then reviewed, and the author terminated his paper by some remarks upon the treatment, among which alkalies, oxide of bismuth, &c., were recommended.

Mr. Hunt considered that this was a subject of great importance, and demanded the most serious consideration of the Society. A friend of his, long a member of this Society, had been attending a lady who had pain in the stomach, but no urgent symptoms; he had recommended her to try change of air, and had said to her that her complaint was of a trifling nature, and would soon be benefited; for a short time she got better, but one day in his presence she suddenly expired; on examining

her body, a hole was found completely circular, as if made with a punch. Another case having a similar termination was related. Mr. Hunt then commended the author for the paper which he had read, but regretted that he had not expended a little time on the primary diseases of that viscus, as he (Mr. H.) thought that, by directing attention to the commencement, many of the most formidable consequences of the disease might be averted. One or two instances were then referred to, where change of diet, &c., had effected a cure.

Dr. Johnson directed the attention of the meeting to the difference of the symptoms in disease existing at the cardiac orifice, and at the pylorus; in the latter, food would remain for some hours in the stomach without being rejected, and without causing any particular symptoms, but after a time pain succeeded, and then the stomach was not at ease until the offending food was ejected. He considered that there was a great difference between the symptoms and pathology of diseases of the two orifices, and ulceration of the coats. The following curious case had occurred in his practice, a young man was seized with excruciating pain in the abdomen after a very hearty dinner, and a rupture, with which he had been some time troubled, became greatly distended. Mr. Stanley visited him, and, recognising the existence of strangulated hernia, proceeded to operate; on opening the sac a great quantity of undigested food escaped, much to the operator's dismay; the patient, however, shortly died, when an ulcer was found to have penetrated the coats of the stomach, and to have allowed of the escape of the undigested food into the abdomen. The edges of this ulcer were thickened, and it had evidently existed some time before it had burst; this was one instance in which disease might go on in the intermediate parts without causing any of the symptoms generally found. One remarkable symptom of contraction and disease of the pylorus was constipation, and the diminished calibre of the stools; frequently also the enlarged pylorus would be found on the left side of the umbilicus or even below it, and was such as frequently to mislead the practitioner.

Dr. Ryan observed, that the author of the paper was entitled to much praise for having brought before the notice of the Society so much valuable information on organic diseases of the stomach, and more specially on the

difficulty of distinguishing them during life. The majority of the profession were too apt to apply the term dyspepsia to all diseases of the stomach, whether a subacute or chronic gastritis, and the various morbid lesions attended by the usual symptoms. It was well known that scirrhus of the pylorus often proved fatal, and that the subject of it had been treated for dyspepsia. He had known two examples of this kind, and was present at the autopsic examinations. He had been consulted within a few days on the case of a gentleman, who was supposed to labour under dyspepsia, and treated accordingly, and desired to go to the country, as very little was the matter with him. He had been ill since Christmas last, and was ordered infusion of cascarrilla, with soda, which very much aggravated his sufferings, and he felt so exceedingly unwell that he sought for other advice. At the time of his application to him (Dr. R.), he complained of pain on pressure along the transverse arch of the colon, at the epigastrium, which was now almost constant. He suffered from flatulence, and the eructation of an acid fluid which produced a burning sensation; bowels open; pulse regular; tongue yellow in the centre and white towards the edges; appetite tolerably good; vomiting once or twice daily; no emaciation; no sleep. Leeches were ordered to the site of the pain, cold water, or barley water, with milk, and the diet to consist of arrow-root, tapioca, &c. The relief he obtained by this plan of treatment was astonishing; and this was observed in several cases of the same kind. He (Dr. R.) had seen the stomach one mass of scirrhus, and its cavity so small as not to contain more than a tablespoonful, though the disease was not suspected during life.

Mr. Johnson wished to ask, if, in the case referred to by Dr. Ryan, the tumour was of a pulpy structure, or whether it had all the characteristics of firm hard scirrhus.

Dr. Ryan replied, that it was true scirrhus.

Mr. Johnson continued, and said the cases which were most commonly mistaken were in his opinion those in which the soft medullary tumour occurred, for it was in this form that the greatest irregularity of symptoms took place; he had observed also that the faeces, as mentioned by his father, were much diminished in size. Speaking of gastritis, he said that, during last year, after the disappearance

of the cholera from the Lock Hospital, almost all the patients had been attacked with mucogastritis, and that in every instance the symptoms had yielded to the application of leeches and counter-irritation.

Some further remarks having been made by several members,

Dr. Johnson said, that perhaps as Dr. Ryan had referred to the distinction between dyspepsia and gastritis, he would favour the Society by relating what were the distinguishing features of the two diseases.

Dr. Ryan said, that the diagnosis between dyspepsia, or functional derangement of the stomach, and gastritis, when the disease was very slight, and confined to a patch or two of small size, was extremely difficult. In cases of long standing, in which the supposed dyspepsia had been treated by tonics, purgatives, &c., and aggravated by these remedies, the symptoms having become more severe, there being pain at the pit of the stomach, or in some other part of the organ, increased on pressure, with cardialgic or burning pain at the cardiac orifice, often compared to that produced by boiling water, melted lead, &c., with nausea, occasional vomiting, and constipation; the pulse being unaffected, no fever present, he should have no hesitation in applying leeches, followed by counter-irritation, the exhibition of cold fluids, low diet, and regulation of the bowels by enemata. He had treated a great number of cases, both in dispensary and private practice, on this plan with success. The diagnosis was, however, extremely difficult in many cases, in which the subjects had not indulged in dram drinking; and here, though the symptoms were often severe, especially in those who pursued sedentary occupations, they generally yielded to purgatives, and tonics, combined with the essential oils, and that very rapidly. In all cases which were aggravated by tonics, spirituous liquors, or purgatives, he was of opinion that there was a greater or less degree of inflammation of the mucous membrane of the stomach, and they ought to be treated accordingly.

Mr. Hunt was of opinion, that the state of the pulse, which was small and sharp, like that indicative of abdominal inflammation, and that of the tongue, which was red in the centre and white towards the edges, afforded a clear diagnosis between dyspepsia and gastritis.

Dr. Ryan replied, that these symptoms were present when gastritis was well established, and when it could not be mistaken; but Dr. Johnson's inquiry was relative to the diagnosis of both, when one was passing into the other, and to this he confined his reply.

Dr. Chowrie was desirous to learn from Dr. Johnson, whether the calibre of the fæces was always diminished in scirrhus of the pylorus.

Dr. Johnson replied, that it was not in an isolated case that he had observed this symptom, but he considered it as generally present, and he thought that the small quantity of nutritious matter conveyed into the intestinal canal, and consequently the diminished call upon the powers of the tube would cause contraction, and thus account for its existence. In reference to what had fallen from Dr. Ryan, he thought that gastritis could not exist without dyspepsia, whilst dyspepsia might be present without gastritis; but he fully agreed with Dr. Ryan, that the result of the treatment was the best criterion of the disease.

Mr. Costello gave notice, that on Saturday next he should perform the operation of torsion upon a dog, after which the meeting adjourned.

MEDICAL SOCIETY OF LONDON.

Monday, February 17th, 1834.

Dr. Uwins in the Chair.

On the Bad Effects of Tea.

MR. COLK, in referring to the discussion which took place at the last meeting on the effects of excessive tea drinking, said he believed it was admitted by all, that the subject was one of considerable importance, inasmuch as it is desirable to know whether an article which we are constantly in the practice of using as diet is wholesome or not; from what had been stated he thought it had been proved that tea produces injurious effects on the nervous system if used in excess. Generally, however, the person, who has been in the practice of taking this beverage, does not suffer from it until his health becomes deranged from some other complaint. He should be glad to hear from any gentleman the result of his experience, either as to the injurious effects or otherwise, of this article, for he had brought forward the subject principally with the view of eliciting information, being well aware that

in spite of whatever opinions they might form on the subject, people would still continue to indulge in what, by most, was considered so great a luxury.

Dr. Uwins said that at all times the subject of diet was one of the greatest importance, and as tea formed so principal an article in our present mode of living, the investigation of its properties deserved the serious consideration of the Society.

Mr. Proctor confessed that to a certain extent he was becoming a convert to Mr. Cole's views; still he could not go so far as that gentleman, but thought that the constitution of the patient, and the time at which the tea was taken, materially influenced its effects. He had made inquiries of a large tea-taster as to the effects on his stomach after tasting great quantities, and had been informed that, usually after so doing, he found his stomach somewhat disturbed. If the tea be taken in a morning on an empty stomach, in large quantities, it will most probably prove injurious, but if used in an afternoon after a hearty meal, it would, in his opinion, rather tend to assist in digestion, as it certainly is (at least in the first instance) a stimulant.

Mr. Kingdon related an instance of a gentleman possessing great alertness and powers of mind, who indulged invariably shortly after dinner in drinking black tea; he had found wine disagree with him, and he confessed that, since making the above change in his beverage, he had found himself quite a different person, but that if he left off the tea after dinner, he could with difficulty apply his mind to any serious occupation. In another case which had lately fallen under his observation, he had attributed the peculiar sensations of fluttering and uncomfortable feeling at the stomach to the use of tea, which the gentleman who mentioned these symptoms was in the practice of indulging in.

Mr. Headland said the numerous and varied effects which Mr. Cole had stated to have followed the use of the article now under consideration, certainly had startled him, and made him hesitate before coinciding in that gentleman's opinions; he thought, however, the part of the paper, in which he alluded to affections of the heart, of considerable importance; in French writings much was said as to gastritis, whilst little mention was made of dyspepsia and its consequences; this rather tended

to favour the views of Mr. Cole in this part of his subject, as it was very well known that tea was used in much greater abundance in this country than by our continental neighbours.

Dr. Stewart thought that tea might be injurious either from peculiarity of constitution, or from excess; the cases related were extremely interesting, since however much we might be inclined to dissent from Mr. Cole's opinions, we must admit that when the tea was discontinued, many of the most prominent symptoms had also disappeared.

Mr. Cole said, in reply to a question as to whether he had ever used porter as an antidote to tea, that he had once used it in the absence of other remedies, but was not aware that it possessed any effects more beneficial than those of other stimulants. A case was related for the purpose of illustrating the irritative influence which tea possesses over the disposition. Instances had also occurred to him, where persons, leaving off the use of tea, had found a certain degree of placidity of temper, unusual to them in their general habits.

Dr. Uwins asked Mr. Cole if, in recommending the discontinuance of this article of common use, he did it with confidence in its remedial effects? Mr. Cole said, in several of the symptoms, such as sinking of the stomach, faintings, and many of the neuralgic affections, he certainly, judging from what he had seen, did feel great confidence in recommending the discontinuance of this beverage.

Mr. Dendy imagined that the effects which tea produced were relative, and not abstract. He bore testimony to Mr. Cole's observations, if they only referred to a few cases, which rarely occurred in practice, but he could not agree with that gentleman if he wished to inculcate the total abolition of the use of this article, as in all cases injurious; with respect to the effects on the disposition from its use, he drew a different conclusion, for many of the Irish labourers, who were unable to procure more solid food, were accustomed to take large quantities of this fluid, and stated that they experienced great gratification from its use. Kæmfer, who spent some time in Japan, has stated that the inhabitants there were in the practice of grinding down the tea and making it into a thick paste, which they take nearly every hour in the day without injury.

Dr. Whiting said that it was necessary that a partial view of this question should not be

taken; in considering the effects of the use of tea, the mode in which it was exhibited must also be brought to mind; no doubt many of the injurious effects resulted from the large quantities of fluid taken into the stomach with the tea; the influence of this was not only in the stomach, but in the system in general, for this fluid was conveyed into the circulation, and would naturally tend to weaken the qualities of the blood; and it was probable that the heart was affected through the medium of this increased quantity of fluid conveyed to that organ. He could not call to his recollection any instances in which irritation had been produced by the moderate enjoyment of this article, but he had seen a contrary effect take place. One remarkable effect of its use was in causing gastrodynia, which he felt some difficulty in accounting for, although he was disposed to think that it was in the muscular coat where the pain occurred.

Mr. Jones wished to ask Dr. Whiting if any particular case occurred to him, where injurious effects were produced by this kind of dilution.

Dr. Whiting said that it would be difficult to take more of a fluid than was beneficial whilst it was in the state in which nature has bestowed it on us: but art had succeeded in so disguising our articles of diet, that unconsciously more might be taken than was beneficial to health.

Mr. Kingdon, Mr. Dendy, Mr. Leese, Mr. Procter, Mr. Jones, and Mr. Yeldon made some further observations on the subject, when Dr. Uwins gave notice, that the anniversary meeting of the Society would take place on the 8th of March. The meeting then adjourned.

THE

London Medical & Surgical Journal
Saturday, February 22, 1834.

**SELECT COMMITTEE—PUBLIC PRESS
—QUACKS.**

On Tuesday last the Committee met for the first time. In the absence of several members, not yet come to town, who take a deep interest in Medical Reform, nothing farther than ordering the necessary docu-

mentary evidence was done. The Committee then adjourned for a fortnight. The public will be soon favoured with a coup d'œil of the jarring elements of charters, statutes, by-laws, and courses of education, which have harassed and distracted the profession from its first cultivation in this country; and many a secret regulation and by-law, which would never have reached the light but in a return, perhaps, to a *mandamus*, will be disclosed.

Since Mr. Warburton has made the revision of the medical laws an affair of state, the most influential and respectable part of the public press has not been silent in impressing upon the public at large the importance of Medical Reform to the well-being of society. The Times, The Herald, and The Globe have lent their characteristic energy to the cause; and, under their powerful advocacy, we have every reason to hope the public mind will be prepared for the reception of a code of laws not unworthy of the interests at stake. We implore the press to continue its valuable exertions to disabuse the members of the legislature of the vulgar errors, which are prevalent about the true nature of our medical dissensions.

In no other country have the laws, for protecting the public health, been so neglected as in this. We expect the Committee will procure correct statements of the laws for the government of the profession in the different states of Germany and in France. It will then be seen how much enlightened foreigners differ from the opinions of some of us, who entertain the singular opinion, that the destructive trade of quackery should not be interfered with by direct legislation. The author of a clever pamphlet* has, by

* Thoughts on Medical Reform. By a Retired Practitioner. Fellowes. 1833.

starting with this position, excited a prejudice against other parts of his speculations, which well deserve mature consideration in remodelling our medical ranks. He thinks that the suppression of quacks, by the force of law, involves the impracticable absurdity of prohibiting a mother, or nurse, from administering medicine to a child suffering from indigestion, till a licensed practitioner has sanctioned the prescription! and that, as every one is allowed to preach the gospel, who can procure hearers, so every one should have liberty to practise physic, who can obtain patients! Is it not surprising, after such an argument for free trade, to find the same writer strenuously contending for the due qualification of dispensers of medicine or medical druggists? We shall, on another occasion, return to the constructive part of the retired practitioner's system, which contains many interesting and useful remarks.

COLLEGE OF PHYSICIANS.—CAMBRIDGE.

A FEW weeks ago we announced the existence of rumours, as to certain changes about to be effected in the by-laws of the College of Physicians; and we pointed out, in a very significant manner to our understanding, the source from which we collected the particulars of so strange an event; that the medical public might not be surprised into a belief, that there was any foundation in fact for our statements, from an ignorance of the source whence we had derived them. It seems a precise acknowledgment of our authority * would have prevented the mistake into which our contemporary charges the medical press to have led the public; for it now appears, in the words of the same journal, that

* The Medical Gazette. See also last number.

“no definite arrangements have been made, or are likely to be made.” At the time, we expressed our suspicions, and deferred some comments on the proposed scheme of alteration, to wait the issue of another week;—the week passed,—the organ was hush,—a serious examination exposed the inadequacy and quackery of the projected alterative; and now the Gazette is at liberty to disown it as emanating from the College, and to repeat the unanswerable objections of the liberal press to such a measure of reform.

The fact is, that some of the Fellows, aware of the impending danger, have evinced a willingness to make some trifling changes, or concessions, in favour of the Licentiates, and to say with Brabantio:—

“We here do give you that with all our heart,
Which, but you have already, with all our heart

We would keep from you.”

and it is not at all improbable, that, among the other secret operations of the corporation, a scheme, not unlike the abortion now dead and buried, was canvassed amongst them. But of this are we certain, that, after no little coquetting,—“She Would and She Would Not,”—Dr. Seymour has the infinite credit of fixing their unsettled purposes; and it is now agreed to stand on the defensive,—to assert the immaculate purity of the College in times past, and rest its claims for future support upon the services it has rendered to medical practitioners; or, should the legislature unfortunately differ from the College in estimating its importance and title to respect, to bow with decent submission to the inexorable decree of fate.

It is impossible to object to the course the College has resolved to pursue at the present crisis: any effort at satisfying the claims of the Licentiates could not now save it from the general investigation

about to be instituted; and any alteration under the present circumstances might appear disrespectful to the Parliamentary Committee, to which it is amenable, and from which the public expects to receive a code of medical law, embracing not only the College of Physicians but every medical corporation in the United Kingdom.

We have this week to record a repetition of bigoted infatuation at the University of Cambridge. A second effort was lately made to induce the University to dispense with her religious tests, in the case of medical degrees, and to throw open her walls to persons of every Christian denomination. This effort was as fruitless as the former: and it now remains for the Committee to decide what medicine has to do with religious profession; and, if the Universities persevere in excluding from their pale the intelligent dissenters of the kingdom,—if the expenses of the Universities are beyond the means of medical students in general,—if any superior privileges are to be conceded to the collateral knowledge, which ought to be acquired at an university,—it will also be its business to decide, whether some other test of superior general qualifications should not be adopted than the possession of a University degree.

COLLEGE OF SURGEONS.

Whilst this body, amongst others, is about to undergo the scrutiny of Mr. Warburton's Committee, and to reveal the *secrets* of its management, a sense of justice compels us to admit that it has latterly exhibited some marks of liberality, and of a deference to public opinion, which distinguishes it from many of its contemporaries. To what this corporate anomaly may be owing, it is not very necessary to inquire. The absence of legal

privileges behind which it might budge itself, and its consequent dependence upon public support, may have induced the majority of its self-elected and irresponsible governors to yield what was untenable: but we are disposed to attribute a little of the merit of its partial reform to a more generous spirit among some of its rulers; which induces us to anticipate the cordial assistance of these latter in the approaching adjustment.

We were led to these reflections at the late public meetings of the College, by comparing what was then passing with the events of a few years ago. The Horatian rule—

“*Posticâ falle Chirurgum*”

has been since abandoned. It is no longer a question whether Portugal-street or Lincoln's-Inn-Fields is the licentiate front of the College; and the habitat of its theatre, whether in the parish of St. Clement's Danes, or of St. Giles Bloomsbury, now concerns none but the parish authorities. To most of our readers these matters of history are familiar*; to some it may be necessary to say, that at the time we allude to, the commonalty of the College were denied admission to its festival meetings by the Lincoln's-Inn-Square door, which was reserved for the exclusives; and that this insulting practical degradation of the members was justified, forsooth, upon the sapient principle that the back door of St. Giles was the front door of St. Clement's! Again, in the times we tell of, when a member slipped in with his hat slouched, and at last dared to hold up his head, and walk straight up to the place where he saw

* The reader will find some of the details in Mr. Salmon's Oration on the Necessity for an entire Change in the Constitution and Government of the Royal College of Surgeons. Whittaker, 1823.

others no better than himself, he encountered a bar which soon brought him to his senses, and convinced him that the man, who lets his nose be pulled with impunity, had better soap it for the next occasion.

The proceedings on the two late meetings were much more decorous; all members were admitted at once by the same entrance upon producing their tickets, and within there was no insulting reservation beyond a decent provision for the governing body. This recognition of the equality of all the members would, perhaps, scarcely deserve the notice we have given it, were it not a partial abandonment of the system of monopoly accomplished by the efforts of Mr. Guthrie, the President, commonly called the Joseph Hume of the establishment, and of such independent members as Mr. Keates and Mr. Vincent, and some others, whose liberal advice will, no doubt, have its due weight with the Committee.

PROVINCIAL MEDICAL ASSOCIATION, MANCHESTER.

A few days ago a meeting of members of the medical profession resident in this town was held at the York Hotel, for the purpose of considering the propriety of forming a provincial society for the advancement of medical science, similar in its design to that which already exists. Among the gentlemen present were Drs. Knight of Sheffield, and Williamson of Leeds; Drs. Hull, Lyon, Shaw, and J. P. Kaye; Messrs. Robertson, Catlow, Gordon, and other surgeons of Manchester. Dr. Hull was called to the chair, and Drs. Knight and Williamson pointed out the causes which had led to the formation of the present design, and the advantages which it was hoped it would possess over the other and more favoured association. It is proposed that the new Society should be confined to Lancashire and the West Riding of Yorkshire, by which means the association would be more accessible to the medical gentlemen of

this part of the country than the one already in existence. It is observed also, that this Society would, in all probability, acquire greater strength than the elder one could attain; that, being of a comparatively local character, it must draw towards it more strongly the interests and sympathies of its members, from the fact, that the local concerns of Lancashire and Yorkshire could be more fully attended to and watched over than could possibly be the case in a society, which had the whole kingdom for its operation, and the members of which were not bound together by those private intimacies, and those professional ties, which unite the practitioners of particular districts. A resolution, expressive of the advantage of forming such an association, was accordingly proposed. It was supported, we believe, by Drs. Lyon, Shaw, and Kaye, and was ultimately carried. Mr. Catlow, surgeon, in expressing his opinions in regard to the scheme, to which he did not give his entire approbation, took occasion to complain of the monopoly which the medical officers of the Infirmary possessed, in having exclusive access to the valuable medical library of that institution, a monopoly which, he contended, was unjust to the great body of professional gentlemen in Manchester, and which ought to be brought to an end. Mr. Robertson expressed his sense of the great benefit which would result from a well assorted medical library in this town, and intimated his readiness to aid in any measures by which such an object could be accomplished. Mr. Gordon opposed the projected medical association, as being not only uncalled for but undesirable. He argued that it was impolitic to diminish the strength and efficiency of the society, which already had been founded under the auspices of Dr. Hastings, by the erection of associations partial in their operations, and limited in their influence, as the one now projected must inevitably be. He contended that the Provincial Medical Association was unobjectionable in its principle, that it possessed all the advantages which could possibly be proposed by this scheme, with many others which it could not possibly attain; whilst the objections which were urged against the elder society (namely, the distance to which gentlemen resident in this vicinity were compelled to travel in order to be present at its meetings, &c.,) were also applicable with

equal force to this design. The Provincial Medical Association was already established and in full operation; it counted among its members many of the most able practitioners in all parts of the country; it was accessible to every one upon easy and equitable terms; and was open to receive the contributions of any gentlemen who might have any information to communicate; and it was therefore impolitic to disunite a body of men who, united, were able to confer such substantial advantage upon medical science, but whose power must ultimately dwindle into insignificance if they were to be cut and carved into county or district associations. The resolution, however, was carried, and we are informed that seventeen gentlemen have enrolled themselves as members of the Medical Association of Lancashire and the West Riding of Yorkshire.

Foreign Medicine.

ACADEMIE DES SCIENCES.

At the sitting of the 27th of January M. Donné presented an essay on the chemical properties of the secretions in health and disease; also on the existence of electric currents produced by the acids and alkalies residing in the different membranes of organised bodies.

The following is a summary of the principal facts which it contains:—

1st. The exterior envelope of the body, the skin, secretes throughout its whole surface an acid humour; nevertheless the perspiration instead of being, as is generally thought, more acid in the axilla, and around the pubis, is, on the contrary, alkaline in these situations, as well as at the toes.

2nd. The digestive tube secretes an alkaline mucus throughout its whole extent, except in the stomach, where the gastric juice is strongly acid.

3rd. Serous and synovial membranes, in their normal condition, exhale an alkaline liquid, which, however, in certain diseases, sometimes become acid.

4th. The external acid, and the internal alkaline membranes, represent the two poles of a pile, the electric effects of which are appreciable by the galvanometer: thus when one of its conductors is placed in contact with the mucous membrane of the mouth, and the other

with the skin, the magnetic needle deviates from fifteen to twenty, and even twenty-five degrees, according to the sensibility of the instrument, and the direction indicates that the mucous or alkaline membrane takes the negative, and the cutaneous membrane the positive, electricity.

Independent of the adverse chemical conditions presented by these two extensive surfaces, other organs exist in the economy, some of which may be styled acid, others alkaline, and which give the same results. For example, very energetic electric currents exist between the stomach and liver in every species of animal.

5th. M. Donné has observed similar electric phenomena in vegetables, on introducing one pole of a galvanometer into the medullary canal, and the other into the rind. These effects are more especially remarkable and defined in the different kinds of fruit. A fruit may be considered as a galvanic pile, the extremity towards the stem being, in adhering fruit, such as the apple and pear, electro-magnetic, and the opposite extremity electro-positive. The contrary occurs in non-adhering fruit, such as the peach and plum. The electric current is not produced in vegetables by their acid and alkaline condition, since the juice of fruits is found on examination to be more or less acid in every part, but it is owing, without doubt, to the difference in the chemical composition of these juices at the two extremities of the fruit.

6th. The acid humours of the animal economy may become alkaline, and the alkaline acid in diseases.

7th. Acidity is most commonly the product of inflammation, properly so called, and this effect may declare itself by sympathy in an organ situated at a distance from the inflamed part; thus in gastritis the saliva becomes very acid.

8th. The acid which is formed during inflammation is, in general, the hydrochloric. According to M. Donné, the presence of this acid determines the coagulation of the albuminous portion of the lymph or serosity, which abounds in inflamed parts. Pus itself is produced by its action on the albuminous lymph. M. Donné adduced numerous cases of peritonitis in which the pus, and even the serosity poured into the abdominal cavity, were found to contain acid qualities.

9th. The alteration in the chemical nature of the secretion re-acts on the different systems of the economy. As regards the etiology, diagnosis, and even treatment of diseases, they form a series of lesions and symptoms interesting to be observed.

Angina Membranacea treated by Cauterisation.

An epidemic of this nature was very prevalent lately in the town of Chateau-Regnault and neighbourhood; it was remarkable that in the town the complaint in the throat was very seldom complicated with scarlatina, whilst in the surrounding villages the two maladies existed together in many persons. It offered in its duration two periods distinguished by different symptoms; in the first it appeared complicated with scarlatina, and was particularly severe with those infants in whom the pharynx was injected, the tonsils swollen, and the uvula inflamed. The inferior part of these three bodies became almost covered with white spots which afterwards extended up the pharynx, covering it to its superior part; the breath became fetid; deglutition impossible, and oftentimes liquids returned by the nose; the respiration became difficult; the voice nasal; there was violent cough, and the patients rapidly perished from asphyxia. In the second period the angina principally affected adults, and commenced with the general symptoms, difficulty of deglutition, pain in the pharynx, and formations of false membranes, which extended throughout the pharynx, and assumed a gangrenous appearance. Some of the patients died from asphyxia, others from cerebral congestion. The treatment, pursued in this complaint with most efficacy, was the employment of cauterisation, and for which purpose M. Gertron preferred in most cases the nitrate of silver; he recommends the adoption of this plan without delay, as soon as any of the white points are perceived either upon the amygdalæ, uvula, or arch of the palate.

Lithotriptical Instrument of M. Ségalas.

M. Ségalas, on the 4th of February, read a memoir on lithotripsy to the Academy of Medicine, in which he endeavours to show by facts the superiority of his instrument over all those which have been employed up to the present time. The cases upon which he founds his claim are to the amount of eleven;

and are of three kinds. First, when the stone is of small dimensions, and can be pulverised at one operation; second, where the calibre of the stone is of moderate size, and requires two or more sittings; and lastly, where it is of still greater magnitude. The two first cases mentioned referred to calculi of the first kind, and were destroyed at the first operation; one was in a young child, the other in an old man aged 70. Amongst the cases of the intermediate description, he cites one where the stone was ten lines in diameter in an old man of 79; another of eleven lines in an old man of 69 was broken at three sittings; one of fifteen lines, complicated with catarrhus vesicæ, was destroyed in three operations. The other cases are more remarkable. Thus in one, the patient, æt. 45, suffered from the presence of a stone of nineteen lines in diameter, and had at the same time acute cystitis. He was freed from the stone at six operations, without any augmentation of the inflammatory symptoms. In one old man, who had a stone twenty-one lines in diameter, the operation was performed without the patient's knowledge; he had refused to submit to the operation, but M. Ségalas, on the plea of introducing only a sound, succeeded in partially crushing the stone; no pain being occasioned, the patient did not afterwards resist, and in six sittings it was completely destroyed.

The most remarkable case was complicated with stricture of the urethra, enlargement of the prostate, and catarrhus vesicæ, the stone was twenty-three lines in diameter, and was destroyed in thirteen operations. The instrument used by M. Ségalas is something like the Percuteur à Marteau of Baron Heurte-loup; but he has added to this instrument a screw, by means of which pressure is made. This pressure being made to a certain degree upon the stone, he strikes a light blow on the moveable blade with the hammer, and then again uses the screw.—*Gaz. Med.*

Replacement of M. Boyer at the Académie des Sciences.

The question which at present attracts the attention of the medical world in Paris, is the election of some person to fill the chair in the Academy of Sciences, vacant by the death of M. Boyer. Seven, if not more, candidates have declared themselves, amongst whom are MM. Patrix, Guérbois, Antommarchi, Velpeau, Lisfranc, Roux, and Brocchi.—*Ibid.*

French Hospital Reports.

HÔTEL DIEU.

Icterus cured by bleeding, purgatives, &c.

A WOMAN, æt. 50, who had been ill some days, came into the hospital under M. Bally; the skin over the whole body was of a deep yellow tint; the conjunctiva was also deeply stained of the same colour, and felt oily; the saliva was green, and the liver evidently was much enlarged; below this organ there was a tumour, caused by the distension of the gall bladder. Percussion discovered slight abdominal effusion; and, by applying the stethoscope, a *râle* was very evident in the thorax. The febrile symptoms were violent, and the pulse was 120.

Bleeding was several times practised; sulphate of soda and large quantities of demulcent drinks were prescribed, and with the most happy effects, for the liver diminished rapidly in volume, the effusion disappeared, the skin quickly regained its natural colour, and at the present time (Feb. 6th) abundant discharge from the bronchial passages is the only symptom remaining.

Remarks.—Referring to this case, M. Piorry remarked, that icterus has been considered most frequently to depend on mechanical obstruction. From numerous cases which he had collected, and from the observations of Morgagni, Stoll, Andral, Cruveilhier, and others, he had arrived at the same conclusion; and thought, that, if moral causes can produce it, it is only by causing some anatomical derangement, which may obstruct the passage of the fluid secreted in the liver.

In our next Number we shall give the result of some further observations, made by M. Piorry, on the causes of obstruction to the passage of the bile.—Ed.

Hysteria — Pulmonary Emphysema caused by the violent struggles made during the paroxysm.

A girl, æt. 17, who had suffered during the last month from violent attacks of hysteria, was brought into St. Lazarus' Ward. She had invariably enjoyed good health, and had regularly menstruated up to the commencement of the attack, which was caused by the brutality of a man who ravished her. The moral perturbation joined to the physical suf-

ferings which she endured were the source of the severe nervous attack which she has since suffered from. The genital organs are much swollen, and, for the relief of retention of urine, which she has, the daily employment of a catheter is required. During the paroxysms, the breathing becomes difficult, the abdomen tumid, and she makes violent but vain efforts to overcome the obstacle which seems to oppose the performance of respiration. These attacks recur many times during the course of the day; and any question touching upon the cause of her complaint never fails to occasion a fresh attack. During the intervals melancholy seems to overwhelm her mind, which is occupied solely with the idea of the loss of her honour, and the destruction of all her future prospects.

On the 29th of January, the thoracic organs were explored with care, during one of the intervals, when it was observed that the right side of the chest was the most sonorous. At this time, however, the respiratory noise was more indistinct, and a slight *râle sibilant* might be heard during expiration. She complained also of cough. On the following day these last mentioned symptoms had vanished. There was then no longer doubt that pulmonary emphysema existed on the right side of the thorax.

The prognosis from this lesion of the lung is very unfavourable; for if these paroxysms do not diminish in intensity, it is to be feared that the emphysema will invade the cellular membrane of the neck and limbs. At present baths and antiphlogistic drinks form the principal part of the treatment.

Case analogous to the preceding—Effect of Imitation.

A damsel, æt. 15, admitted for slight typhus fever, and placed in a bed near to the above patient, has been attacked with similar hysterical symptoms, evidently caused by the proximity to the former case.

Remarks.—This influence of nervous imitation has been observed by most authors who have written on this subject. It once reigned to a great extent in the hospital at Leyden; and Boerhaave, who was then attached to that institution, had recourse to the following mode of stopping the contagion. He directed a chafing dish to be placed in the ward, and, having heated an iron, threatened to apply it

to the next patient who should offer these paroxysms. This menace was attended with the most happy results in young girls, but in older persons, who probably did not believe in the truth of the threat, it completely failed.

British Hospital Reports.

WESTMINSTER HOSPITAL.

Enlargement and Irritability of the Mamma.

— JONES, a healthy, good looking young woman, æt. 19, was admitted into this hospital, having her right breast exceedingly enlarged, and endowed with a most exquisite sensibility. The least pressure on the part was attended with the most acute pain, rendering her existence very miserable.

Soon after her admission she was put on the extract of belladonna, in the quantity of one-fourth of a grain three times a-day. The tinctura lyttæ and oleum terebinthini were also administered. An ointment, composed of acetate of morphine and adeps, was used as a topical application.

Under this treatment the patient has experienced very beneficial effects, the enlargement of the breast having been considerably diminished, and the morbid sensibility, which it formerly possessed, being removed.

Enlargement of the Tonsils—Incision.

A young man came to the hospital some time ago with his tonsils very much enlarged. Deglutition was rendered very difficult, and his breathing was much impeded. Mr. White, on seeing the case, desired incisions to be made in the tonsils, which treatment was followed by Mr. Finch.

Incisions were made every alternate day in the tonsils, which were eventually cured by this mode of treatment.

LECTURES
ON THE
PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY;
BY PROFESSOR SAMUEL COOPER.
*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXVIII., DELIVERED MARCH 29, 1833.

GENTLEMEN,—Although I have in previous lectures called your attention to various tumours, which are strictly *new productions—adventitious growths*—not having constituted any portion of the original structure of the body, I have not yet given you any account of the formation and characters of tumours in general.

In proceeding through the subjects of diseases of the bones, I described certain morbid formations, which are comprised under the preceding definition; as for instance, exostoses, and fibrous and medullary growths from the medullary membrane. In the account of cancer, fungous hæmatodes, and melanosis, I have also partly travelled through the subject of those tumours, which, at least in some of their forms, are regarded as new productions in the system, and not merely as changes of structure, or as augmentations in the bulk of original tissues, for they comprehend several of those formations which are denominated *heterologous*, and which our distinguished Professor of morbid anatomy describes as consisting “in the presence of a solid or fluid substance, different from any of the solids or fluids which enter into the healthy composition of the body.” Professor Carswell’s definition will include, however, calculous and purulent deposits, which, though they are heterologous formations, it is advantageous not to arrange them under the head of tumours. While some of the growths, also, which I regard as tumours, correspond to the foregoing definition in not being like any of the original tissues of the body, others bear more or less resemblance to some of its primitive structures. Tubercle, scirrhous, and melanosis, are examples of the first; adipose and cartilaginous swellings, of the second. In fact, as Andral

says, with reference to such of these depositions as become organised, when once vessels are developed in the morbid product, or sanguineous currents are established in it, the amorphous mass begins to lose its homogeneous nature, and to assume some definite kind of texture. The anatomical elements may now take the arrangement of fibres, layers, coats, or of a net-work; and they may put on the appearance of any of the normal structures, excepting two—the muscular and nervous.

Our profession is under many obligations to the late Mr. Abernethy, for drawing its attention very particularly to the great difference between tumours of the above nature, and other swellings which are merely alterations of natural structure, or sometimes only the consequence of the accumulation of blood, pus, or other fluid in parts, and which last cases in particular have no claim to be considered as tumours, under the principle of classification suggested by Mr. Abernethy. This was, unquestionably, making a bold step, out of all the confusion in which this part of the pathology of surgery used formerly to be involved. Nobody can doubt that the distinction here laid down is a good one, and that all swellings of original parts, to which no new morbid-tissue has been added, and which consists rather of alterations of natural structures, or of the accumulation of pus or other fluids in them, than of the growth of any adventitious substance, should not be confounded with tumours, in which the latter circumstance is exemplified. The swellings of arteries, termed *aneurisms*, the knotty enlargements of veins, called *varices*, and all tumours arising from accumulations of blood, pus, or serum, in natural cavities and tissues, as well as a multitude of other examples, in which the tumour or swelling, does not strictly consist of a new formation, growing upon, or amongst, or added to, the original parts and tissues of the body will not be comprised in Mr. Abernethy’s classification.

If there were not some limitation assigned to the surgical meaning of the word *tumour*, every disease, whatever might be its nature, if accompanied by increased fulness, or enlargement of parts, would be arranged under this head, whether an aneurism, a phlegmon, an

erysipelas, a boil, a carbuncle, an abscess, or a dropsy. In truth, such is the miscellany, which you will find adopted in old works, and which should not be called an arrangement but a chaos.

As, however, we find the heterologous matter deposited not merely upon free substances, like those of serous or mucous membranes, or within the cells of the cellular tissue, but likewise deposited in the molecular structure of organs, after the manner of nutrition, it is manifest, that, when original parts become enlarged in the latter way, the disease ought to rank as a tumour, according to the principle of an adventitious substance being added to its primitive tissues. In this point of view, Abernethy's arrangement is not satisfactory, and so little was it suited for practical purposes, that he deviated from it himself almost as soon as he had explained it, by considering as tumours carcinomatous and different sarcomatous affections of several original parts, where the enlargement depended upon the molecular deposit in their tissues.

Tumours, in general, are divided into the *sarcomatous* or *fleshy*, and the *encysted* kind, many of the latter being familiarly termed *wens*, and consisting generally of a more or less fluid or fatty substance in a globular cyst; while the sarcomatous swellings are usually solid, and when they have a cyst, which is not always the case, it is not that regular, complete, and globular sac, commonly exhibited in a true encysted tumour. By a sarcomatous tumour is meant one that is chiefly or entirely composed of a fatty, fibrous, medullary, fungous, or other substance of inferior hardness to bone.

An *encysted* tumour is composed of a regular cyst, or sac, filled with matters of very different kinds in different examples, which matters are commonly secreted by the cyst into its cavity. The contents are not always fluid, being sometimes of a pultaceous consistence, sometimes like horn or bone, and, in other instances, like adipose substance. Frequently the cysts are filled with a fluid resembling honey or white of egg; and occasionally they contain melanotic matter, and even hair, or teeth. You will also frequently meet with cysts, which serve as lodgments for hydatids.

Some of the *solid sarcomatous tumours* are encompassed by a kind of cyst, by a dense cellular substance, which yields, and becomes thicker and thicker as the tumour increases in size, and appears to form a sort of barrier between the new morbid formation and the healthy parts, so as to protect the latter in some degree from the extension of the diseased action to them.

Some *solid sarcomatous tumours* have no such limit, but extend in the direction in which there is the least resistance, and soon transmit their morbid action amongst the surrounding parts. Others have no tendency to communicate any diseased action to the rest of the body; but only become dangerous or annoying by their bulk and pressure. Some

sarcomatous tumours grow rapidly, and prove troublesome in a few weeks or months; others remain for years without much change or inconvenience. The texture of some of these tumours bears more or less resemblance to that of the neighbouring parts; thus, fatty swellings frequently grow in situations, where they are surrounded by the natural adipose tissue. Cartilaginous tumours, as you know, are often produced within joints, where they become detached from the articular cartilages, and a cause of pain and lameness; and tumours of a cellular structure internally, and covered by a mucous tissue, frequently grow from the surface of mucous membranes. But, gentlemen, you are not to consider the resemblance of the substance of a tumour to the nearest tissues as an invariable principle; for many swellings not only have a different structure and appearance from those of the adjacent parts, from whose vessels they derive their supply of blood, but from every other healthy and natural tissue in the body.

Mr. Abernethy not only proposed the restriction of the meaning of *tumour* to what is truly a *new and adventitious formation*, and not simply a *change or enlargement of an original tissue*, but he suggested the plan of naming every tumour according to its anatomical structure. Thus he first applied the term *medullary sarcoma* to what is also called *fungus hæmatodes*. That, and some other names, which he selected, appear to me appropriate enough; but fault may be found with others; and his nomenclature, however ingenious, has the defect of not being altogether consistent. Thus, as it was designed to be one, founded upon the anatomical structure of tumours, the term *cancerous sarcoma* is not admissible. I should say, also, that as the generality of sarcomatous tumours have vessels, the phrase *vascular sarcoma* is not well chosen to express only one species of the disease.

One fact, perfectly established, is, that some kinds of sarcoma are merely new formations, unconnected with any *malignant tendency*, or any thing particularly wrong in the constitution. Thus common adipose swellings only become troublesome by their size, weight, and pressure; but a scirrhus, a fungus hæmatodes, and, perhaps, a melanotic tumour, though this may be doubted, are malignant diseases. Certainly each and all of them, inclusive of melanosis, are associated with constitutional derangement or peculiarity, the precise nature of which may not indeed be known, but of the existence of which not a doubt can be entertained. The distinction between *innocent* and *malignant* tumours, important as it is with reference to practice, and especially with reference to the propriety of operations and the mode of doing them, is yet a subject involved in the greatest obscurity. Tumours, which in their regular progress destroy life by the changes produced in the affected part, such as ulceration, bleeding, and sloughing, or by causing similar productions in other parts of the body, more par-

ticularly in important internal organs, or by both together, are considered to be *malignant*; and the occurrence of serious, local, and general symptoms, the development of new growths in other parts, and such constitutional suffering as leads to the suspicion, that organs of consequence are involved in the affection, are generally set down as decided proofs of malignant character, and as insuperable objections to an operation. Yet, much caution is required in giving an opinion on the malignancy of some tumours.

The *tuberculated sarcoma*, as it was called by Mr. Abernethy, is represented by him as a very malignant disease; yet, in one example of it, recorded by Mr. Lawrence, where the original tumour had a most threatening aspect, where several similar tumours presented themselves in other parts, and where the patient had been brought to the brink of the grave by constitutional disturbance, life was prolonged for many years by amputation.

Some of the heterologous formations are organised and vascular; others are completely free from organisation, and are furnished with neither vessels nor nerves. They seem to be merely morbid products from the blood, only deposits produced in the manner of a secretion, and frequently from a serous surface.

With respect to the origin of vascular tumours, we have little information that can be supported by demonstration, or even by arguments unexposed to disputation. It is a subject that was lately considered by Mr. Lawrence, in a paper read to the Medical and Chirurgical Society. In this ingenious production he inquires into the mode in which tumours originate and increase, and adverts to the three explanations usually offered of the phenomena:—1. By the effusion of blood, and its coagulation, and the subsequent organisation of the coagulum. 2. By the effusion and organisation of coagulating lymph. 3. By chronic inflammation. Now, if these explanations were true, we should expect, with Mr. Lawrence, that tumours ought to pass through successive stages, and to present different appearances at different periods of their development. For instance, we ought to find them at first as masses of coagulated blood, or coagulating lymph, and then to observe various degrees of transition from those substances to the textures, which characterise the perfect growth. Observations, however, disclose nothing of this kind: tumours, in their earliest state and smallest size, have their peculiar structure as well marked as in their subsequent progress and full development. An adipose tumour, not exceeding the bulk of a pea, differs only in size from one as large as the head. Effusions of blood into the cellular texture, from external violence, are of daily occurrence; if they could become organised, and then form tumours, few persons would be without these productions, which would also be, from the first, as large as the extravasation. We see, however, that blood, thus poured out,

disappears by absorption, or irritates the surrounding parts, and causes suppuration, by which it is expelled.

The hypothesis of the formation of tumours, by the effusion and organisation of blood, seems, indeed, to have little foundation; and, I think, we must agree with Mr. Lawrence, that no satisfactory proof exists of blood becoming organised, when effused in wounds, bruises, or serous cavities, or aneurismal sacs.

The interstitial effusion of lymph in inflammation is a thing noticed every day; the substance, thus poured out, is not formed into tumours, but is absorbed as the inflammation subsides, or its partial organisation causes the enlargement, or condensation of the affected structure. Then, none of the phenomena, characteristic of inflammation, commonly precede the formation of tumours, which arise insensibly, and often attain some size, before the patient is aware of their existence. Besides, as is well observed by Mr. Lawrence, if the accounts given of the origin and growth of tumours were correct, the attempts to check their production by leeches, cold applications, and antiphlogistic treatment would generally have more effect than we find to be the case. Such treatment has no influence over accidental productions, though sometimes employed with advantage in lessening swellings caused by changes of structure.

The best pathologists are then in a state of ignorance respecting the circumstances, which determine the production of tumours in general, or of any particular variety of them. No more is known about these aberrations of nutrition, than of the mode in which this function is accomplished in its natural or normal state.

Adipose sarcoma, or the *fatty kind* of solid tumour, is the most common of all these new formations. In its appearance and structure, it has a near resemblance to the subcutaneous fat, but is of a somewhat deeper yellow colour, less granular, and more compact. Adipose sarcomatous tumours are always covered by a thin capsule, formed by the simple condensation of the surrounding cellular tissue, and having but a slight attachment to the fatty mass itself, by means of very small vessels. It is in consequence of these circumstances, that adipose tumours admit of removal with considerable facility, and, after a sufficient division of the skin, the diseased mass may be readily detached from the surrounding parts, sometimes with the fingers, and always without any troublesome dissection.

You will find these fatty growths existing frequently in persons, in whose constitutions no particular defect can be discovered; and sometimes they occur, not merely in one situation, but in several, though the individual may be in other respects perfectly healthy. They are generally attended with little or no uneasiness, and are characterised by a soft doughy feel, or one as if they were filled with wool. They have no disposition to become dangerous by changing into any malignant

form of disease; and whatever pain and inconvenience they may produce, are the result of their weight, pressure, and magnitude, for adipose sarcoma is generally inclined to grow to a larger size than any other solid kind of tumour met with in the human body. I have seen one or two examples which weighed nearly fifty pounds, and larger ones are upon record.

They are sometimes the seat of uneasy sensations, never malignant, though occasionally attended with shootings, and they may interfere more or less with the free action of the neighbouring muscles.

Now, gentlemen, when it is recollected, that the operation for the removal of an adipose swelling of immense size may prove fatal from the unavoidable extent of the wound,—when we also remember, that you have no means of dispersing a fatty swelling, that if left to itself it is sure to acquire considerable magnitude; and that when of immoderate size, it is apt to become closely adherent to fasciæ, and even to the capsular ligaments of important joints, so as to render its complete removal difficult; you must see the prudence of always taking away an adipose sarcoma, while it is small and but loosely attached to the surrounding parts. Adipose sarcoma does not, like a malignant tumour, require the free removal of the adjacent textures.

The *pancreatic sarcoma*, so named by Mr. Abernethy, from a degree of resemblance in its structure to that of the pancreas, is rather an uncommon disease, and scarcely any unequivocal specimen of it has been preserved in any of the museums of the metropolis. One was exhibited last winter at the Medical and Chirurgical Society's house as a rarity, and even that was considered by some gentleman present as having much of the appearance of ordinary scirrhus. Mr. Abernethy represents pancreatic sarcoma as occurring sometimes near the nipple, and sometimes in the lymphatic glands on the mylo-hyoideus muscle, and as an irritable and excessively painful affection.

Some instances of pancreatic sarcoma have been met with by Mr. Lawrence. They were formed, either close to the parotid gland, or under the jaw close to the sub-maxillary gland. Pancreatic sarcoma is loosely connected with the surrounding parts, and therefore very moveable; a character in which it is said to differ from scirrhus, though we know that scirrhus, in its early stage, is frequently as moveable as any other kind of swelling. In Mr. Lawrence's cases, the disease was free from pain and malignancy, and effectually cured by operation. The pancreatic sarcoma, which Professor Carswell arranges in his *Illustrations of the Elementary Forms of Disease* as a species of cancer, does not at all correspond to the disease noticed by Mr. Lawrence; and, as a foundation for classing the disease with cancer, he refers to its disposition to terminate in the gradual destruction or transformation of the tissues affected, its

tendency to affect several organs in the same individual, and its reproductive character.

Another species of sarcoma described by Mr. Abernethy is the *mammary*, from the likeness of its structure to that of the mammary gland. It appears to be malignant, communicating to the surrounding parts a disposition to disease, and requiring the same free removal of them in an operation as a scirrhus, of which I suspect that it is only a modification. In corroboration of this opinion, I may observe, that Professor Carswell, in his invaluable *Illustrations of the Elementary Forms of Disease*, actually arranges mammary sarcoma as a species of cancer.

The *tuberculated sarcoma*, consisting of numerous firm globular swellings, of various sizes and colours, connected together by cellular membrane, advances to ulceration, is a malignant disease, and ultimately proves fatal. It is questionable, I think, whether this form of sarcoma is essentially different from scirrhus, which, we know, has its varieties.

A species of sarcoma, with which surgeons have long been familiar, is described under the name of *cellular tumour*, consisting of a fleshy mass, elastic, and almost fluctuating to the touch; tough, fibrous, and chiefly composed of condensed cellular tissue free from fat, the fluid in the cells being like that of the common cellular membrane.

Between the cellular tumour and the enormous swelling, in which the male organs of generation are sometimes involved, Mr. Lawrence conceives that there is this distinction,—the former is a new production, the latter merely an enlargement of the cellular and cutaneous tissues by interstitial deposition, curable by extirpation.

The *Fibro-cartilaginous tumour* is another variety of sarcoma, not unfrequently met with about the head, neck, and axilla; and sometimes grows near the mammary or parotid gland. It differs from scirrhus in having nothing malignant in its nature; the only inconvenience is what results from its pressure and size.

About two years ago, I removed a swelling of the fibro-cartilaginous kind, from the occiput of a blacksmith at Halliford. It had been stationary and free from pain for many years, but at length began to enlarge and cause a great deal of annoyance. It was as large as an orange; and the patient was induced to have it removed, in consequence of his suspicion that a difficulty of swallowing, which he laboured under, was dependent upon it. The latter affection ultimately proved fatal, however, and on opening him, a stricture of the oesophagus was found, with two considerable sacs extending from the tube above the obstruction, in one of which were two orange pips.

The *painful subcutaneous tumour, or tubercle*, was particularly described by Mr. Wood, in the 3rd vol. of the *Edinb. Med. Chir. Transactions*. Although of small size, and free from malignant action, it is attended

with most excruciating pain, it is generally situated in the cellular membrane under the skin, but sometimes in that which is between muscles. One tumour of this kind, removed by Mr. Liston, lay so deeply, that it was in contact with the posterior tibial nerve. The tumour is usually of the size of a pea, and seldom larger than a cherry. It is not very prominent; the skin is loose and moveable over it, and its structure is almost like cartilage. The reason of its causing the extraordinary degree of pain by which it is characterised, has been ascribed by some pathologists, amongst whom is the celebrated Camper, to its connexion with the twigs of the sub-cutaneous nerves. It is indeed declared, that filaments of nerves can not only be traced upon its surface but within its substance.

Camper's opinion, that the tumour depends upon a diseased enlargement of a portion of a subcutaneous nerve, has been almost universally adopted, and is that to which Mr. Wood himself inclines, though he thinks it very desirable, that additional minute and accurate examinations of the tubercles and surrounding parts, should be made, with the view of ascertaining, if possible, whether the diseased alteration of structure takes place on the neurilema, or within it; or whether it may have originated in the contiguous textures, and become afterwards connected with the nerve. In those painful tubercles which he had an opportunity of examining, he found only a firm, whitish, homogenous body, of a fibro-cartilaginous appearance, without being able to say whether it was included between the nervous fibrils or not, or whether it was even positively connected with them.

The pain comes on periodically, and shoots extensively through the limb. The slightest pressure causes the most excruciating torment, and such is the agony sometimes caused by the action of the muscles, that the use of the limb is entirely lost. The disease is more common in the extremities, particularly the lower ones, than other parts. There is only one right and effectual treatment, namely, excision.

Gentlemen, I must next call your attention to *Nævi*, and the Tumours termed *Aneurisms by Anastomosis*.—Certain natural textures in the body are, in the ordinary state, flaccid, but admit of being rendered turgid and firm at particular periods, when they become injected with blood. You will find examples of this kind of structure in the penis, clitoris, and nipple; and by French anatomists it is termed the *erectile tissue*. Baron Dupuytren compares the tumours, which usually go under the name of *nævi*, to a *morbid erectile tissue*; and, as far as I can judge, there is a sufficient resemblance between the natural tissues of this kind, and the structure of *nævi* to justify the comparison.

Under the head of morbid erectile tissues may be arranged,

1. The Superficial Nævus.
2. The Subcutaneous Nævus, and Aneurisms by Anastomosis.

Gentlemen, I will first speak of *superficial nævi*, or *nævi materni*, as they are called, signifying those congenital tumours, spots, or imperfections and peculiarities in the appearance and texture of parts of the skin, which are vulgarly supposed to arise from some influence of the mother's mind upon the fœtus, as when during her pregnancy she *longs* for various delicacies and fruits, which she is not able to procure, or, at all events, which she cannot obtain so quickly as she desires. Or, perhaps, during her pregnancy, she is terribly frightened at the sight of a spider, mouse, or some other animal; and then, whatever cutaneous mark the infant is born with, is imputed to such disaster. As a proof of the truth of the connexion of the *nævi* with such longings or frights, a strong resemblance is often fancied between these maternal spots and the objects of desire or alarm. Thus some *nævi* with a granular surface are compared to strawberries, mulberries, or raspberries, and are supposed to become particularly red and conspicuous when those fruits are in season. Others have a reticulated appearance, produced by the ramifications of minute vessels on their surface, and being thought to resemble a cobweb, are named *spiders' nævi*. Then you will meet with other congenital blemishes of the skin, which, on account of their peculiar red colour, are called *claret marks*. Another common form of *nævus* is, what you must be familiar with, as receiving the name of a *mole*, in consequence of its brown colour, and the long hairs growing upon it. Objects of this kind always present an opportunity for a flight of the imagination, and for the invention of comparisons and names.

These superficial *nævi* frequently continue stationary during life, and neither increase in size nor cause any inconvenience; but sometimes, in consequence of their happening to be situated on the face or neck, they cause considerable disfigurement, and, with the view of removing or lessening it, the excision of the blemish may be undertaken if desired.

Examples do occur, however, in which these maternal spots assume, after birth, a disposition to grow, and even to acquire considerable size. In this circumstance, it is prudent to recommend excision of the tumour, which, as it is only cutaneous, may be accomplished with safety and facility. I have known some of them disperse after inflammation had been excited in them, by inserting vaccine lymph in them, or by touching them with nitric acid or a strong solution of nitrate of silver, or rubbing them with this substance. I lately attended an infant for a *nævus* situated precisely over the fontanelle, or unossified part of the cranium above the os frontis. Apprehending that excision might produce more bleeding than so young a child, only four or five months old, might be able to bear, I held a consultation with Mr. Wormald, of London, and Mr. Harcourt, of Weybridge, and then passed a double ligature through it as deeply as seemed prudent. This destroyed the greater

Part of the nœvus; but a trivial portion of it escaped the constriction and began to grow with great rapidity, so that in a week the swelling was nearly two-thirds of its original size. We now attacked the disease freely with the nitrate of silver, which produced ulceration, and the effect of this and of subsequent pressure soon completed the cure. This case, however, was a subcutaneous nœvus, and consequently more difficult to cure than the superficial kinds.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE X.

Nature and Treatment of some of the Diseases of the Large Intestine.

GENTLEMEN,—To-day we proceed to the consideration of the nature and treatment of some of the diseases of the large intestine. You will see in the various systematic treatises on the practice of physic separate descriptions of the affections of this portion of the digestive tube, you will find diarrhoea in one chapter and dysentery in another, and you will observe, that a great deal of ingenuity has been expended in forming nosological differences between these affections. I fear that much of what has been written respecting them is rather calculated to puzzle and mislead than to inform the student. Viewed anatomically there is no essential difference. You may for every practical purpose place them in the same class, and consider them as the result of the same morbid condition of the same part, namely, an inflammation of the lower portion of the digestive tube. Some persons may quarrel with the term inflammation,—call it then irritation if you please, but the truth is, that it is disease of the lower portion of the intestine, the results of which are increased sensibility and altered secretion, and this description, I think, will fairly apply to one as well as the other. If a man has purging with fever and pain it is called dysentery, if he has purging without pain, and without any manifest febrile excitement, we call it diarrhoea. But, in cases where persons have died, after having laboured under diarrhoea for a length of time, we generally find, on dissection, lesions of the mucous membrane of the intestinal canal, sufficient to account for death. There are some cases indeed, in which the mucous surface takes on a gleet discharge, similar to that which follows gonorrhœa, and under such circumstances you will not be able to discover any distinct anatomical evidences of disease. These, however, are comparatively rare, and bear little or no proportion to those cases which present distinct traces of organic lesion.

On the subjects of diarrhoea and dysentery I shall be very brief, as our time is short, and every thing relating to the pathology and treatment of these affections may be expressed in very few words. First, then, as to diarrhoea, which is the frequent passing of stools of a more or less watery consistence, and which may, and generally does occur without fever. This affection may be considered to arise under three different circumstances, but, in point of fact, every form of the disease may be referred to a single cause, as there is no essential difference in the actual nature of the circumstances by which they are produced. A patient, for instance, takes a quantity of indigestible food, this produces irritation in the gastrointestinal mucous surface, and diarrhoea is the consequence. Another is exposed to cold, or gets wet feet, the mucous membrane of the bowels becomes more or less inflamed, and this terminates in diarrhoea. Again, a patient, labouring under hectic, has profuse perspirations, these go off and are replaced by frequent fluid discharges from the bowels,—here, also, the result is called diarrhoea. All these forms are, however, referable to the same cause,—irritation of the mucous lining of the digestive tube.

A man commits an excess at table, eats something that he cannot digest, and gets diarrhoea. If you happen to be called to such a case at an early period, your course is very plain and easy; there is every chance that the affected organ has received (as yet) no material injury, and it is attempting to relieve itself by increased secretion. The indication here is to get rid of the source of irritation as soon as possible, and this is best done by prescribing a laxative to remove the offending matter, and then following it up with an opiate. The simple rule is to relieve the intestine, and prevent the liability to inflammation. A mild laxative, followed by opiates and demulcents, keeping the patient on a low regimen for a few days, and in a warm temperature; this is sufficient for the management of the first form of diarrhoea. In point of fact, the principal thing, which the practitioner has to do, is to watch his patient, and take care not to permit the inflammatory action to become developed. It is in such cases as these that the expectant medicine is of value. What you are to direct your attention to, is the state of the intestinal surface. If a patient gets an attack of pain, if his belly becomes tender on pressure, if he is more or less feverish, you may be sure there has been some mischief done. If, on the contrary, the diarrhoea yields to the exhibition of a mild laxative and light diet; if the pulse soft and the belly not tender you have no reason to fear. But if the purging becomes more distressing, if the pain is severe, the abdominal tenderness evident, the thirst and restlessness continue unabated, it is a sign that the irritation has produced something more than mere increased secretion, and that actual disease of the mucous tissue is setting in. We have now a true inflammatory diarrhoea, which may be

looked upon altogether as an enteritis of that kind, in which there is a copious secretion from the surface of the intestine. You observe this leads us at once to the principles of treatment. Here we have fever, pain, frequent morbid stools, thirst, and abdominal tenderness. Well then, what are you to do? In a case where these symptoms are so severe as to excite alarm, at once begin by applying leeches. Where there is merely evidence of intestinal irritation caused by indigestible food, give a laxative, and follow it up with an opiate; where, in addition to the ordinary symptoms, you have fever, pain, and tenderness, never omit the application of leeches. Many a time have I seen cases of this kind, in which chalk mixture and astringents not only failed but even caused additional suffering, speedily and completely relieved by the application of a few leeches. In using leeches, too, we are not, like the practitioners who trust to astringents, playing at the game of double or quits; nor do we stop the purging by exchanging it for something else equally bad, or even worse, for a peritonitis or a bronchitis for instance; *by removing its cause we not only check the diarrhoea, but we obviate any tendency to a metastasis of inflammation to other tissues, and our mode of cure has at once the merit of being successful and safe.*

A patient who has had an attack of diarrhoea should have his belly swathed with flannel;—this should never be neglected. He will also experience a great deal of benefit from the use of the hip bath and occasional opiates. Give also a combination of rhubarb and Dover's powder, and you will find that it will do him a great deal of good. This is the remedy which Rhoderon and Wiegler found to be of extraordinary advantage, in the mucous fever with diarrhoea which ravaged parts of Germany in the last century. Give two or three grains of each every second or third hour, and increase or diminish each of the ingredients according to circumstances, increasing the Dover's powder where the indication is to remove pain and irritation, and increasing the rhubarb where you wish to produce a laxative effect. This combination forms a remedy of decided value in enteric inflammations; it has been much used in such cases by Dr. Cheyne, and I have repeatedly employed it in the Meath Hospital with marked advantage. You are also to bear in mind that though the principle of treatment in this disease is to remove its cause and put a stop to the purging, still you are in no case authorised to give it a sudden check by astringents in the early period. I gave the reasons for this at my last lecture, and showed that it was based upon a general law of the economy. If an organ in a state of inflammation pours out an increased quantity of secretion, *it is the mode in which nature attempts to give relief, and if you suddenly arrest this secretion, the probability is that you will excite more inflammation in that organ, or cause a me-*

tastasis to other parts. This is particularly the case if inflammatory fever exists. You must also attend to your patient's diet. Your object here is to support him on such a diet as will require but little digestive power, and will not produce large collections of fecal matter in the bowels. Jellies, arrow-root, chicken-broth, and mild farinaceous food are the only things that can be used with safety, until the intestinal irritation has subsided.

By pursuing this plan of treatment with steadiness and decision, you generally succeed in cutting short the disease. In some cases the diarrhoea will run on to the chronic stage, just like the gleet which follows gonorrhoea; and this is to be looked upon as the apyrexial period, in which antiphlogistic remedies are no longer admissible, and where you may employ stimulants and astringents with effect. The best way to manage this form of the disease, is to make your patient use warm clothing, an even temperature, and mild nutritious diet; to prescribe the vegetable and astringent tonics, the hip-bath, and the occasional use of mild laxatives, followed by an opiate. In this way, after some time, the disease generally goes off, and the patient recovers his strength. But it may happen that this gleety discharge will continue unabated; it is running the patient down, and he wants some decided remedy to check it. Now the remedies which appear to have the greatest power in stopping this discharge, are the metallic astringents, and the turpentine and balsams, combined with some of the preparations of opium. It is a curious and interesting matter to consider how these remedies act. They are a class of medicines which exercise an extraordinary influence over discharges from mucous surfaces, in a way we do not understand, but the effect is to arrest these discharges. In a case of ophthalmia, accompanied by copious secretion from the conjunctiva, or in a case of chronic gonorrhoea, we know there is nothing more beneficial than metallic astringents and balsams; and we are also aware of the great value which turpentine and balsam copaiba possess in checking the increased expectoration of a chronic bronchitis. In diarrhoea, also, they have the same power; they check inordinate secretion, and remove the morbid condition of the mucous membrane on which it depends, by some effect produced on the surface of that membrane, but in what manner this is accomplished we know not. In severe cases of this gleety discharge, one of the most certain remedies we can employ is acetate of lead. You will seldom have occasion to use this or any of the other remedies alluded to, in the case of a healthy person, because the disease will seldom pass into this second or gleety stage, but if it should, and that it is running down the patient, it behoves you to check it as soon as possible, consistent with safety. Give then the acetate of lead in free and repeated doses, and it is singular to re-

mark what quantities of it patients under such circumstances will bear without any bad consequence ensuing. Hitherto many persons have been afraid to employ it in large quantities, from fear of producing painters' colic; but at present it is known that this disease is to be attributed to the absorption of the carbonate of lead in almost every instance, and that the acetate is comparatively harmless. On this point I can mention one interesting fact, namely, that I have been in the habit of using it constantly, and in considerable doses, for the last six years, and I cannot bring to my recollection one single instance of colic produced by it. One patient in particular, who was under my care, took it in very considerable doses for six weeks, without any apparent injury. The only cases, in which I have seen the acetate of lead act as a poison, were those in which it had been used as an external application. Whether it be that this remedy is more pernicious when employed after the endermic mode, or whether, when applied to the skin, it attracts carbonic acid from the air and is converted into a carbonate, I do not know, but of this I am certain, that where bad effects have followed the employment of the acetate of lead, they have been brought on by its external use. I generally use this remedy in the form of pill, prescribing two grains of the acetate of lead and a quarter of a grain of opium, three times a-day. With the same intention you may employ the turpentine and balsams, which have a powerful effect in checking mucous discharges. Dr. Pemberton, in his work on Abdominal Diseases, speaks very highly of the efficacy of balsam copaiba; and I have seen many cases where turpentine has had a great efficacy in arresting chronic diarrhoea. You will see, in the works on materia medica, some other remedies which you can employ with benefit in such cases, but I may mention one which is not generally known,—the alkali of the nux vomica. Strychnine was first used in checking mucous discharges by a German physician, and afterwards by Dr. Graves in this city. The cases, in which it proves most successful, are those in which there is a mere gleety discharge, a copious secretion from the mucous surface without any inflammatory action whatever, or if there be, where it is so low as not to produce the least feverish excitement or pain. Cases of this kind, in which strychnine has been eminently successful, have been published by Dr. Graves. Among others is that of a gentleman, who had sudden calls, so that he often had not time to reach the close-stool. He passed a quantity of thin jelly-like substance, and then experienced a transient relief until another attack came on. This case was cured by the use of strychnine, one-twelfth of a grain, three times a-day, made into pills with crumb of bread or aromatic confection.

I may mention here, that, in treating gleety diarrhoea in this way, one thing should be

always borne in mind,—it is always dangerous to check any copious secretion suddenly, and the danger consists in the liability to metastasis or new inflammation. Never forget this. What generally happens is, that the patient's belly begins to swell, and you have ascites rapidly formed. Now, I have never seen a case do well in which this kind of ascites came on after the sudden checking of a diarrhoea, the patients all died. Another consequence is the rapid supervention of pulmonary inflammation, and here the disease is almost as bad as in the bowels. You will ask how this unfavourable termination may be avoided. The best mode is, while you are arresting the discharge from the bowels, to promote a determination to the surface. While you are using opiates, and stimulants, and astringents, employ general warm bathing, or the hip bath, dress the patient in flannel, and use mild diaphoretics every night. You will also do right in blistering the belly occasionally. In this way you will succeed in curing the worst cases of this chronic flux, without exposing your patient to the risk of new inflammation, or translation of disease to other organs.

One of the most common forms of diarrhoea is the purging which occurs in cases of phthisis; a physician will be called to treat this as often as any other, and it is of importance that you should have correct ideas with respect to its pathology and treatment. The ordinary opinion is, that this kind of diarrhoea is one of the results of hectic fever, and many practitioners, in treating the purging of consumptive patients, overlook the actual condition of the intestine, and only take into consideration the state of the whole constitution, of the hectic state of which, the diarrhoea is looked upon as one of the symptoms. The consequence of this is, that they do not proceed on the same principles in the treatment of this as of other similar affections of the intestinal canal. Now I would impress upon you, that you should always consider the diarrhoea of phthisis as depending in almost every instance on enteric inflammation. There is no fact in medicine better established than this. Persons think it is the hectic which produces the purgation, but I believe the converse of this proposition is often much nearer the truth, and that the constant diarrhoea often produces and keeps up the hectic. If you examine the digestive tube of a patient who has died with symptoms of phthisical diarrhoea, you will commonly find extensive ulcerations in the colon, cæcum, and ileum. In some cases of consumption, where the purging has been very severe, the amount of disease will often be found to be quite extraordinary; I have often seen the whole of the lower part of the tube one sheet of extensive ulceration. I find I have not brought up any specimens of the effects of phthisical diarrhoea from the museum, but will exhibit them at our next meeting. The preparations before us are those which are illustrative of dysentery, but they

will convey to you a good idea of the state of the great intestine in the diarrhoea of consumption, for the effects are nearly the same. Observe now, gentlemen, the importance of this fact, and recollect that in treating every case of consumption with diarrhoea you will have constantly to bear in mind this enteric complication. Recollect, also, that one of the best means of stopping it, when all other remedies have failed, is a blister applied over the abdomen. If the purging depended on hectic this would not be the case. I could bring forward several cases in which every thing had been tried without success, when a blister was applied to the belly, and from the time it rose, the patients ceased to be troubled with diarrhoea, and continued so up to the period of death. I do not mean that you should in these cases proceed to attack the enteritis with the same vigour as you would a similar disease in the healthy subject. Generally speaking, I believe this form of enteritis to be incurable, but it is of importance that you should be aware of this enteric complication in phthisis, and when you are called in to treat such a case, you should carefully avoid prescribing any thing calculated to add to the existing irritation.

Before I quit this subject, I wish to make one remark by the way of caution. It not unfrequently happens that a person, labouring under chronic diarrhoea, comes to consult a medical practitioner, and tells him that he has been suffering from this complaint for months, that he has eight or nine discharges by stool in the day, and that he has been under the care of five or six doctors in succession, without any benefit. Well, you are determined to have your trial too, and you commence operations by putting him on full doses of acetate of lead. After a week or a fortnight he comes back and tells you he is not a bit the better. You then try turpentine or balsam copaiba—no use. Nitrate of silver—the same result. The man gets tired of you in turn, and perhaps goes to a surgeon to ask his advice. The surgeon examines the rectum carefully, and finds, at a short distance from the anus, an ulcer, which he immediately touches with a strong solution of the nitrate of silver. The ulcer begins to heal, and accordingly as it heals, the irritation of gut ceases, and the diarrhoea goes off. The surgeon is extolled to the skies, and the doctors disgraced for ever in the opinion of the patient. Now this is not an uncommon case. I have seen several instances of it, and I must tell you I was once mistaken in this way myself. These ulcers are situated close to the verge of the anus, they occur chiefly in persons of broken-down constitution, and those who have taken a great deal of mercury. They produce irritation in the colon, tenesmus, griping, frequent discharges by stool, and, most commonly during the straining, a little blood is passed. During the course of last summer, I treated a soldier for this affection, who had been discharged

from the East India Company's service (as was stated in his discharge) for incurable dysentery. I examined the rectum, and finding some ulcers close to the anus, had them touched with the nitrate of silver. Under this treatment a rapid amendment took place, and in the space of three weeks the man was discharged quite cured. Now, are you to make this examination in every case? I believe you will act rightly in doing so in every case of chronic diarrhoea in the male, but the examination is absolutely necessary in all cases under the following circumstances: first, when the diarrhoea has been of long standing; secondly, when it has resisted a great variety of treatment; thirdly, when it is combined with tenesmus and a desire of sitting on the night-chair after a stool has been passed, showing irritability of the lower part of the great intestine; and lastly, when the patient's health does not appear to be so much affected as it naturally should be, where there was long-continued disease of a large portion of the great intestine. A patient will come to consult you; who will inform you that he has had eight or ten alvine evacuations every day for the last six months, and yet he eats heartily and looks quite well. Under these circumstances, the cause of the diarrhoea will generally be found to be ulceration of limited extent low down the tube, and capable of being quickly and effectually removed by a strong solution of the nitrate of silver. I shall recapitulate all the circumstances under which an examination is indispensable; where the symptoms have been persistent, have resisted a variety of treatment, are accompanied by tenesmus, and where the injury done to the general health is not in proportion to the duration of the disease. I may mention here, that a medical friend of mine has communicated to me the particulars of another case of this form of diarrhoea in a soldier who was invalidated on this account, and who experienced sudden and permanent relief from the application of nitrate of silver to some ulcerated spots which were discovered near the termination of the rectum.

We come now to the subject of *dysentery*. I shall draw your attention briefly to the general principles of the pathology and treatment of this affection; but I do not intend to enter upon the consideration of its general history which you will find sufficiently detailed in books. The first principle I have to enforce on this subject—and you may take it as an observation based on the soundest pathology—is this, that dysentery is inflammation of the large intestine. In some cases it is complicated with fever, and in others with disease in the upper portion of the digestive tube; and I believe that those cases, which are termed *epidemic dysentery*, are those in which this disease is combined with typhus fever, or with an extensive affection of the small intestine—where there is ileitis as well as colitis. I shall not take up your time with discussions respect-

mark what quantities of it patients under such circumstances will bear without any bad consequence ensuing. Hitherto many persons have been afraid to employ it in large quantities, from fear of producing painters' colic; but at present it is known that this disease is to be attributed to the absorption of the carbonate of lead in almost every instance, and that the acetate is comparatively harmless. On this point I can mention one interesting fact, namely, that I have been in the habit of using it constantly, and in considerable doses, for the last six years, and I cannot bring to my recollection one single instance of colic produced by it. One patient in particular, who was under my care, took it in very considerable doses for six weeks, without any apparent injury. The only cases, in which I have seen the acetate of lead act as a poison, were those in which it had been used as an external application. Whether it be that this remedy is more pernicious when employed after the endermic mode, or whether, when applied to the skin, it attracts carbonic acid from the air and is converted into a carbonate, I do not know, but of this I am certain, that where bad effects have followed the employment of the acetate of lead, they have been brought on by its external use. I generally use this remedy in the form of pill, prescribing two grains of the acetate of lead and a quarter of a grain of opium, three times a-day. With the same intention you may employ the turpentine and balsams, which have a powerful effect in checking mucous discharges. Dr. Pemberton, in his work on Abdominal Diseases, speaks very highly of the efficacy of balsam copaiba; and I have seen many cases where turpentine has had a great efficacy in arresting chronic diarrhoea. You will see, in the works on materia medica, some other remedies which you can employ with benefit in such cases, but I may mention one which is not generally known,—the alkali of the nux vomica. Strychnine was first used in checking mucous discharges by a German physician, and afterwards by Dr. Graves in this city. The cases, in which it proves most successful, are those in which there is a mere gleety discharge, a copious secretion from the mucous surface without any inflammatory action whatever, or if there be, where it is so low as not to produce the least feverish excitement or pain. Cases of this kind, in which strychnine has been eminently successful, have been published by Dr. Graves. Among others is that of a gentleman, who had sudden calls, so that he often had not time to reach the close-stool. He passed a quantity of thin jelly-like substance, and then experienced a transient relief until another attack came on. This case was cured by the use of strychnine, one-twelfth of a grain, three times a-day, made into pills with crumb of bread or aromatic confection.

I may mention here, that, in treating gleety diarrhoea in this way, one thing should be

always borne in mind,—it is always dangerous to check any copious secretion suddenly, and the danger consists in the liability to metastasis or new inflammation. Never forget this. What generally happens is, that the patient's belly begins to swell, and you have ascites rapidly formed. Now, I have never seen a case do well in which this kind of ascites came on after the sudden checking of a diarrhoea, the patients all died. Another consequence is the rapid supervention of pulmonary inflammation, and here the disease is almost as bad as in the bowels. You will ask how this unfavourable termination may be avoided. The best mode is, while you are arresting the discharge from the bowels, to promote a determination to the surface. While you are using opiates, and stimulants, and astringents, employ general warm bathing, or the hip bath, dress the patient in flannel, and use mild diaphoretics every night. You will also do right in blistering the belly occasionally. In this way you will succeed in curing the worst cases of this chronic flux, without exposing your patient to the risk of new inflammation, or translation of disease to other organs.

One of the most common forms of diarrhoea is the purging which occurs in cases of phthisis; a physician will be called to treat this as often as any other, and it is of importance that you should have correct ideas with respect to its pathology and treatment. The ordinary opinion is, that this kind of diarrhoea is one of the results of hectic fever, and many practitioners, in treating the purging of consumptive patients, overlook the actual condition of the intestine, and only take into consideration the state of the whole constitution, of the hectic state of which, the diarrhoea is looked upon as one of the symptoms. The consequence of this is, that they do not proceed on the same principles in the treatment of this as of other similar affections of the intestinal canal. Now I would impress upon you, that you should always consider the diarrhoea of phthisis as depending in almost every instance on enteric inflammation. There is no fact in medicine better established than this. Persons think it is the hectic which produces the purgation, but I believe the converse of this proposition is often much nearer the truth, and that the constant diarrhoea often produces and keeps up the hectic. If you examine the digestive tube of a patient who has died with symptoms of phthisical diarrhoea, you will commonly find extensive ulcerations in the colon, cæcum, and ileum. In some cases of consumption, where the purging has been very severe, the amount of disease will often be found to be quite extraordinary; I have often seen the whole of the lower part of the tube one sheet of extensive ulceration. I find I have not brought up any specimens of the effects of phthisical diarrhoea from the museum, but will exhibit them at our next meeting. The preparations before us are those which are illustrative of dysentery, but they

will convey to you a good idea of the state of the great intestine in the diarrhoea of consumption, for the effects are nearly the same. Observe now, gentlemen, the importance of this fact, and recollect that in treating every case of consumption with diarrhoea you will have constantly to bear in mind this enteric complication. Recollect, also, that one of the best means of stopping it, when all other remedies have failed, is a blister applied over the abdomen. If the purging depended on hectic this would not be the case. I could bring forward several cases in which every thing had been tried without success, when a blister was applied to the belly, and from the time it rose, the patients ceased to be troubled with diarrhoea, and continued so up to the period of death. I do not mean that you should in these cases proceed to attack the enteritis with the same vigour as you would a similar disease in the healthy subject. Generally speaking, I believe this form of enteritis to be incurable, but it is of importance that you should be aware of this enteric complication in phthisis, and when you are called in to treat such a case, you should carefully avoid prescribing any thing calculated to add to the existing irritation.

Before I quit this subject, I wish to make one remark by the way of caution. It not unfrequently happens that a person, labouring under chronic diarrhoea, comes to consult a medical practitioner, and tells him that he has been suffering from this complaint for months, that he has eight or nine discharges by stool in the day, and that he has been under the care of five or six doctors in succession, without any benefit. Well, you are determined to have your trial too, and you commence operations by putting him on full doses of acetate of lead. We come now to the subject of *dysentery*. I shall draw your attention briefly to the general principles of the pathology and treatment of this affection; but I do not intend to enter upon the consideration of its general history which you will find sufficiently detailed in books. The first principle I have to enforce on this subject—and you may take it as an observation based on the soundest pathology—is this, that dysentery is inflammation of the large intestine. In some cases it is complicated with fever, and in others with disease in the upper portion of the digestive tube; and I believe that those cases, which are termed *epidemic dysentery*, are those in which this disease is combined with typhus fever, or with an extensive affection of the small intestine—where there is ileitis as well as colitis. I shall not take up your time with discussions respect-

ing epidemic dysenteries, or those of warm climates; it will be sufficient for the present to allude to that form of disease which is observed in this country.

I have told you that dysentery is an inflammatory affection of the great intestine, and all the symptoms during life, as well as the phenomena revealed by dissection, tend to confirm this view of the subject. We often have fever because the constitution sympathises with the inflammation of an important organ; we have excessive pain and irritation of the intestine, in consequence of its muscular fibres being involved in the inflammation; and we have discharges of morbid, purulent, and bloody secretion. You will now please to inspect this preparation, and hand it round. See the effects of dysentery—the extensive inflammation, ulceration, and sloughing of the mucous membrane. Here is another preparation; you perceive the whole surface of the colon is covered with coagulable lymph, which, in some cases, forms a chief part of the dejections. Here is a preparation which exhibits extensive sloughing of the mucous membrane; its tissue, you see, is quite abraded and destroyed. Here is a preparation of chronic dysentery, which presents a very curious appearance; the mucous membrane is finely mamillated, as it were, and it is stated on the label, that the process of cicatrisation was going on. If you compare it with the others, you will find a remarkable difference. Here is another specimen of dysenteric destruction.

Here, then, is a disease in which we have violent inflammation of the mucous membrane and submucous cellular tissue, and, in severe cases I believe, of all the coats of the great intestine, except the serous. Let us rehearse its symptoms briefly. Fever of an inflammatory or typhoid character, great pain and excessive irritability of the great intestine, morbid discharges of purulent, bloody, and lymph matter, twisting pains called *tormina*, and frequently the absence of fecal matter in the dejections.

At my next lecture I hope I shall be able to finish this subject, and I shall then bring before you some remarks on constipation and collections of air in the great intestine, two points upon which much light has been lately thrown.

CLINICAL LECTURES

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, &c. &c.

At the Westminster Hospital.

LECTURE X.

On the Anatomy and Diseases of the Bladder and Urethra.

GENTLEMEN,—The symptoms of stricture, like those of most other diseases not imme-

diately affecting life, are often as slow in their progress, and as insidious in their nature as they are appalling in their results. They may be divided into several stages, both with reference to the age of the patient, and to the nature and duration of the complaint. When a young man has suffered from a long continued gleet, in the manner I have already described, he is in all probability first alarmed by a partial retention of urine; from having been obliged to make his water on the first sense of desire taking place, and which he could not restrain for an instant, he finds he cannot now pass it except by drops, or with great straining, or perhaps not at all. This usually occurs after a debauch, and is generally relieved by the warm bath, or hot fomentations to the perineum, and a gentle dose of medicine, and the patient is equally aware of the cause and of the means of relief. This is the first inflammatory stage attended by thickening only of the mucous membrane, and admits of his sometimes evacuating his urine in what he calls a full stream. On this point, however, persons are always deceived; they never duly estimate the size of the stream they formerly made or now make, and when they are cured they always express their surprise at the difference which has taken place, and their astonishment that they should not have perceived the alteration. It is only when a great change has occurred that the sufferers are aware of the fact. The discharge, which it is probable may be but trifling, glues the sides of the orifice of the urethra together, and the urine which passes first in the morning often comes from this cause in a double or forked stream, whilst at others it is quite natural. The desire to make it is more frequent, and the patient has to get up at night sometimes four or more times instead of sleeping the usual number of hours quite soundly, although its evacuation is rarely accompanied by pain, unless the prostatic part of the neck of the urethra, or the neck of the bladder are particularly affected. The more anomalous sensations differ much from each other. Some persons feel only generally debilitated, others suffer from flying pains in the hip, a sort of weight in the pelvis, with uneasiness in the perineum, and there is a very marked symptom which frequently prevails in more permanent and irritable strictures, viz. a pain extending from the perineum down the inside of the left thigh, and which occurs very rarely in the right, although I know not why it should be so. When the derangement has become a permanent stricture, the patient is much less liable to a sudden attack of dysury, or retention of urine, than he was in the mere inflammatory stage, but the stream of water has become less, and he is sensible of the more frequent desire to pass it, and that it is longer in flowing, although a smaller quantity is made at a time. He is also aware that he can repeat the attempt in a less space of time than formerly; for unless the bladder has become more than ordinarily irritable, the whole

of its contents are not discharged, but only such quantity as relieves the urgency of desire. There is still a discharge, and it is often this that makes the sufferer apply for advice, rather than the other symptoms. When the disease is more advanced, the urine flows only in a very small stream, either twisted, forked, double, broken, or passing by drops, and the patient is even obliged to solicit and assist its passage by pressing with his finger in the perinæum, and at the same time elongating the canal, something in the way, as a gentleman said to me, a dairy woman milks a cow. When the disease has reached this point, the urethra may have become dilated behind the stricture, and some water remains in the dilated part after the bladder has ceased to act, and this dribbles through the stricture, keeping the patient wet and uncomfortable, and often excoriated. This symptom is experienced in a less degree at a much earlier period, and the younger patient often complains of the longer time he is obliged to occupy than formerly, in getting rid of the last drop of water. This inconvenience sometimes remains when a man is apparently cured, and can pass a full-sized bougie with only a slight sensation when it goes over the part affected. This some patients expressively enough call *back water*, and it occurs either from there being a small bank of stricture remaining, or from that particular part, in which it was situated, having its natural elasticity impaired. This is the last symptom to be removed, and it is never effectually done unless every vestige of disease has disappeared. The straining, which is necessary to expel the urine through a very narrow opening, brings into action the abdominal muscles, and this often gives rise to a rupture, by which the maladies of the unfortunate patient are augmented, and he is obliged to encumber himself with a truss. His miseries are only, however, now beginning; the excessive actions of the abdominal muscles lead to a corresponding relaxation of the sphincter ani, and the feces pass in small quantities, involuntarily, during the effort, the mucous membrane of the bowel protrudes, and this protrusion sooner or later, combined with bleeding piles, augments his distresses, which are even increased from time to time by an irritation of the whole of the mucous membrane of the bowel, which sympathises with the urethra, and occasionally causes a diarrhoea, which, whilst it augments all his evils to a point almost unbearable, is often removed as by a charm, by any thing which will allay the irritability of the stricture. Hitherto we have attended to one function only of the urethra, its second and hardly less important one in middle life shares alike in, and adds to, its difficulties. In the early stages the irritation of the prostatic part of the urethra and of the neck of the bladder, with which in structure and function it is inseparably connected, leads to the increased desire to make water, and the establishment of chronic inflammation; these react on the diseased part of the urethra in

front, and materially augment the mischief. The orifices of the prostatic ducts inflame and enlarge; the inflammation extends to the glandular structure itself, even if it has not been sympathetically affected previously, the emission of semen is attended by excruciating pain, a dull heavy weight referred from the perinæum to the part, and an especial tenderness in the rectum when the prostate is touched mark the progress of the evil. The irritable state of the habit is immediately augmented; a cold shivering occurs, followed by heat; these are repeated and fever is fairly established; the secretion of the liver is principally deranged, and vitiated bile is discharged in great quantities; the fever at last gradually diminishes, although it does not entirely subside, and assumes more of an intermittent type, but not before a greatly augmented discharge of matter from the urethra marks the opening of an abscess of the prostate into it, or a tumour in the rectum, or perinæum, indicates its probable evacuation in these directions, and which must be assisted by art. The cup of misery is not yet full. The bladder partaking of disease may either be very much thickened and diminished in size, as well as acutely or chronically inflamed, or it may be augmented in size without being materially thickened. When the disease in the urethra has been rapid in its progress and acute in its symptoms, the bladder more often partakes of the first state; when the disease causing it has been slow in its progress, and situated at the neck of the bladder itself, or in the prostatic part of the urethra, it has appeared to me to be more often of the second. In either case the desire to make water is continual, the irritable state of the neck of the bladder and part immediately adjacent allow scarcely a moment of rest, and if pouches have formed in it, every turn of the restless individual renders his desires more urgent, by emptying these pouches of their contents. Worn down by his sufferings, in the agony of despair he prays to God for his dissolution, and if it has pleased the Almighty to weaken his intellectual faculties, as it has been his will to afflict his bodily powers, he sometimes becomes forgetful of his duties, and seeks in laudanum, or other narcotics, a temporary solace, which he hopes and expects may prove in this world eternal.

The testes at an early period of prostate irritation often partake of disease. This has often been supposed to depend on sympathy, but I apprehend, and am inclined to believe with Mr. Abernethy, that it occurs from the continuous propagation of irritation from the opening of the ejaculatory ducts in this part of the urethra. The testes become uneasy, then painful, and a little swelled. In warm climates it usually terminates in hydrocele, with a softened and enlarged, or sometimes a hardened and enlarged testis. In more northern climates, abscess occasionally takes place, or chronic induration is sometimes mistaken for scirrhus. Some of the most brilliant cures I

have been the means of effecting in surgery, have been made in cases of this nature.

When the obstruction to the passage of urine is nearly complete, the violent efforts made to discharge it bring on ulceration, and some parts yield. The bladder has been said to burst, but this is of very rare occurrence indeed. I have known the bladder ruptured by a fall from a height when a quantity of urine was contained in it, but not solely from its own action, or from over distension. Mr. Brodie has alluded in his work to two cases, which occurred in St. George's Hospital, of this kind; but these, or others of a similar nature, are only rare exceptions to a general rule, that the urethra yields before the bladder, when the urine is effused into the surrounding parts, giving a temporary relief, to be followed by more fatal symptoms, unless the science as well as the art of surgery be brought to the assistance of the sufferer. The surgeon may at this moment prove a guardian angel, one single thrust of a lancet, in the proper direction, may suffice, and the unhappy man, groaning in the utmost agony, is at once relieved, and placed in comparative safety, whilst in a few minutes more, the rupture of the urethra and the extravasation of the urine places him in a situation from which he will never probably be extricated, or only after much suffering. The urine is forced into the cellular membrane with all the power of the bladder acting spasmodically: the instant the rupture of the urethra takes place, the patient is relieved by the extravasation; he is sensible that his urine is flowing from his bladder, he hopes he is passing it, as the accident usually takes place in a moment of great straining and agony, but on looking down, he perceives with alarm the scrotum and the neighbouring parts greatly distended. He is, however, for the time relieved, the extraordinary excitement of the bladder ceases, and as the pressure and irritation on the posterior part of the stricture are partly taken off, the urine even dribbles through it, exciting hopes which are not likely to be realized. The white doughy feel of the scrotum assures the surgeon of the danger of his patient; he hopes yet by several free incisions to save him; but if he is not called until the skin of the scrotum, of the penis, or of the lower part of the abdomen, has taken on an erysipelatous blush, he will be, in all human probability, too late. The cellular membrane has lost its life, and must slough away with its covering skin, under which, and indeed before this process is completed, he sinks and dies. Mortification in these cases often rapidly supervenes, black patches appear in different places, the febrile symptoms are momentarily augmented only to be depressed, and the same symptoms of anxiety and distress, which supervene in all other cases of mortification, await in this. The cessation of pain, the extreme exhaustion, the inexpressible anxiety of countenance, combined with clearness of intellect, mark in the

most fatal manner the nature of the case, and the patient's expression of his sanguine hope of recovery is only interrupted by the dim shadows of approaching death, which cast a blueness and a film on surrounding objects, which he himself observes and complains of, and but too ineffectually attempts to remove; or if his powers have been more slowly exhausted, he gradually sinks into a state of coma, or low muttering delirium, and dies.

This rapidity in death is not always so great; the ulceration of the urethra may be slower in its progress, an abscess forms external to it or to the bladder, the contents are then discharged, either naturally or artificially, and a passage through is thus established for the urine, and several fistulae in perinaeo or above the pubes or in the groin are or may be the result. This also, in middle aged or elderly persons, or those of bad constitutions, is often attended with great danger; a high degree of fever supervenes; cold shiverings mark the formation of matter; the pulse becomes as quick as it is small and irritable; the tongue gradually assumes a brownish colour, and is dry to the appearance as well as touch; the countenance changes to a dingy yellow, a reddish spot forms on the cheek, and if the abscess is not early opened, and relief in this way obtained, the patient equally, although less rapidly, sinks and dies. Its contents are always dark coloured, and unhealthy and foetid, indicating the urinous participation in its contents.

In some few cases, but which I hope may always in future be obviated, the stricture is never so very complete but that some urine can find its way through it, and, by the great effort and urgent solicitations of the patient, it passes in a small, wiry, spiral, and often unconnected stream; more often by drops; or rather it dribbles away, forcing the patient, in better circumstances, to wear a bag to receive it; whilst the poor man, on whose clothes it falls, is rendered an object of abhorrence to himself as well as to all around him. It is with regret I recal to my recollection the situation of an officer, a captain of the navy, whose urethra I opened too late, some years ago, to bring the desired relief; and who, by the present improved modes of treatment, would, I am persuaded, have been saved. His bladder was enlarged, as it usually is in these cases, and was never completely emptied, although the urine constantly dribbled away. Affected by chronic inflammation of its mucous membrane, the urine was and is always, in these cases, loaded by a viscid muco-purulent deposit; and which, from its long retention, has often partly undergone that decomposition, which renders it offensive in more than an ordinary degree.

When the irritation is entirely chronic, the thick, white, viscid secretion predominates; when it is more or less acute, the muco-purulent. When chronic from time, but acute from suffering, the quantity of this kind of matter

discharged is quite surprising. I attended a friend of mine, a clergyman, for more than three years, who had also the assistance of every surgeon of eminence in London,—he died under the care of Dr. Prout and myself; and we both suspected there might be ulceration of the bladder, but dissection showed only the internal membrane of a dark red colour, thickened, and coated in patches by fibrine. I had cured him three times in earlier life of the same complaint, the fourth attack was always irrelievable by all the various means employed. In this case, and in all others of a similar nature, the mischief is not confined to the bladder, if the disease continues for any length of time. The ureters and kidneys become affected, and the destruction of the latter takes place in a variety of ways. It is usually supposed that these alterations of function, as well as of structure, begin not from the kidney sympathising with the bladder and urethra, in the same manner as the testes have been presumed to be affected, but by the extension of inflammation from the lining membrane of the bladder to that of the ureters. Without denying that this may be the case in some instances, I am not disposed to believe that it is the most frequent or common cause of such disease taking place in all. In the generality of these, the disease of the kidney is accompanied by more or less of dilatation of the ureter; and, from the views I have entertained of the manner in which the urine is admitted into the bladder, I suspect that it is the dilating and dilated state of the ureter which gives rise to the mischief in the kidney. In other words, the accruing difficulty to the ingress of urine into the bladder, whilst the kidney continues to secrete it, causes distension of the ureter, pressure on the tubular as well as the secreting parts of that organ, and ultimately chronic or acute inflammation, ending in absorption of its substance, dilatation, abscess, or other lesions of structure usually found in these cases.

If an abscess, under any of these circumstances, should lead to a communication between the urethra and rectum, the misfortunes of the individual are complete. The future offers to him but little prospect of health, of comfort, or of happiness; for, although I have known some instances of a cure being effected under these deplorable circumstances, the generality of sufferers have had, for the remainder of their lives, to bemoan their miserable existence, and to pray for its speedy termination.

On the method of examining the Urethra.

When it becomes necessary to examine the urethra by the bougie, in order to ascertain the nature of the disease existing in it, the surgeon should regulate his proceedings by the age and the symptoms of the patient. If he be a young man, suffering but little, and making his water in a tolerable stream, a solid silver sound is the best instrument, because it

will always pass with much less pain or inconvenience to the patient, and is less likely to be interrupted in its progress by any of what are called natural obstacles. It should be well oiled, smaller at the point than in the shaft, and of a size to pass very readily into the orifice, whatever the size of it may be; it is to be, in fact, not more than two-thirds of the size of the canal. If the urethra is sound, this will meet with no obstacle, give no pain, and only cause a feeling of desire to make water as it passes through the prostatic part of the passage, accompanied by a sense of faintness, if it has been passed for the first time, but which does not always occur, and will not recur after two or three trials. If it only gives rise to soreness or pain when passing on, or rather over, the part particularly affected, and its progress is continued without inconvenience, it shews by this the portion of the urethra which is suffering from chronic inflammation. If the sound stops at the spot, instead of passing over it, and only proceeds after a little pressure, it indicates a thickening of the mucous membrane, and a probable loss of elasticity of its external covering, constituting what is called a dilatable stricture. It is not often that a derangement of this kind is found after the first six inches and a half, and when none is discovered in this space, the complaint is in all probability in the prostatic part, or from seven to eight inches, or even nine, as the case may be. If the instrument passes without obstruction, but with a pain which is often so very severe as to make the patient exclaim not only of it, but of the desire to make water, the disease is in the membrane of this part, and may extend by continuity of structure to the neck of the bladder, and which will be shown by its irritable state, and the urgency of the calls to rise at night to evacuate its contents. If the sound is arrested at or about seven inches, and after some difficulty, and on withdrawing it and depressing the handle, it then passes on into the bladder, the complaint is, in all probability, an inflammatory swelling of the transverse portion of the prostate, and must be treated very gently and cautiously, by abstaining from the use of instruments, or by using them very rarely, and at long intervals. In the former case of prostatic membranous inflammation, the solid sound should be laid aside, and the cure completed by the small soft bougie, which is to be carefully and very gradually increased to the full size of the orifice. When the obstacle to the passage of the instrument exists at the very entrance into the bladder, which is known first by the resistance at from seven and a half to eight or even nine inches in different persons, and by the peculiar sensation communicated by it to the hand as it enters the hollow bladder, the elasticity of the neck of this organ is impaired, but not irrecoverably so. The patient will in this case not only have a frequent desire to pass his urine, but will find it very difficult to do it; and even when a No. 12 can be passed, he will sometimes be unable to evacuate his

bladder but by drops, and at last not at all. With a narrow stricture the young man makes a stream, however forked, spiral, or small; in this complaint he can scarcely make it at all, and at last cannot do so, and is to be relieved by the catheter. I have never seen this disease in a person under twenty-six years of age, and it is more common between thirty-five and forty-five, although when once formed it will continue through life unless relieved.

When a young man has a permanent stricture, the sound, if small enough, passes through it, giving to the hand of the surgeon the sensation of going over a ridge; and it is quite curious to observe how small an increase in the size of the instrument will often prevent its progress under any reasonable pressure. After a little time the obstruction becomes greater, and the opening narrower, so that the instrument which passed on the first trial will not go through after the violence offered by the larger one. The face of the permanent stricture will, in fact, not yield, yet if a smaller pointed conical instrument be insinuated into it, it will then give way by its inner circumference, but not by its surface, and a larger instrument will then go through without doing much mischief if it does no good. If the bougie hesitates, and afterwards passes on extending the pendulous portion of the urethra, and thus putting it on the stretch, it has in all probability hitched on a fold of the urethra; and if a small pointed instrument is used, and is arrested at a particular spot, whilst a larger and round pointed one passes over it, the obstacle is most likely caused by an enlarged orifice of a follicle, and which will bleed freely if the pressure of the small bougie be continued. If the larger bougie passes over a spot which is exquisitely painful, and which bleeds, it will often lead to the suspicion of an ulcer; and if much blood flows without any obstruction, or there is only a sort of hesitation, a soft fungous growth may have taken place from it, such as I have already described.

When a moderate sized bougie will not pass, and the diminished stream of urine leaves no doubt of the existence of a narrow stricture, a smaller bougie must be had recourse to; and if the obstacle is evidently before the curve of the urethra, or five inches and a half along the canal, the instrument, whether solid or soft, should be straight, and must be used with a light and gentle hand, by which means, and after several trials with the point turned in different directions, it may perhaps meet with the opening of the stricture and pass through. Too much, however, should not be done at one essay, pressure on the face of a stricture with any kind of bougie, I have already said, does more harm than the passage through it of a larger one. In these cases it will be necessary to take an impression of the face of the stricture, in order to discover where the opening is situated, by which means the point of the instrument may be more certainly di-

rected to it. This is accomplished by means of a middle-sized bougie made of soft materials, the point of which is first softened by dipping it into hot water, when it is well oiled, passed down to the stricture, against the face of which it is to be gently but steadily pressed. If the stricture, although narrow, is not very tough or permanent, it will sometimes yield, and the softer bougie goes through, when the point of the harder one only turns back, the bougie having doubled on itself in the passage. If the stricture does not yield, the soft bougie does, and is gradually pressed into the sinuosities or openings on its surface, so that after remaining some minutes, it is withdrawn, with one or more processes projecting from the end of it, either acute or obtuse, as the case may be, and indicating the commencement of the true, and sometimes, also, that of one or more false passages. The experience of the surgeon will now be his best guide; and he will remember that this obstacle is much more often below than above, and that a channel in that direction is much more often a false than a true one. Messieurs Ducamp, Lallemand, and Phillips recommend for this purpose a bougie, the end of which is particularly soft, by being made of a quantity of cotton threads drawn through an elastic bougie hollow at each end. The cotton threads, when nearly drawn through, and only a small portion projects, are to be dipped into a composition composed of equal parts of bees' wax, empl. plumbi or diachylon, and cobbler's wax, and are to be rolled in the usual way, until the bougie appears smooth, round, and of an equal size. The French make this soft part too long, and they are therefore objectionable as imported from Paris, inasmuch as they bend more than is necessary, and leave a portion of the composition behind and in the stricture, giving rise, as Lallemand has himself shown, to great inconvenience and even distress. This is, in some degree, avoided by making the cotton thicker, and the soft point altogether shorter. The desired information being gained and the size of the opening ascertained, its passage is to be attempted by some duly selected instrument, of a firmer material, of plaster, of catgut, or caoutchouc, which last will be without comparison the best, if the obstruction be situated at or near the curve. It is not, however, an easy matter to hit the small opening, and many efforts may be made in vain, until at last one better directed or more fortunate succeeds. If by a bougie it should be allowed to remain in for an hour, and if a catheter it should be kept in altogether, unless the bladder is peculiarly irritable, and then it need not be carried into it, but be firmly fixed an inch beyond the stricture. This method is not however necessary, and is often so inconvenient to the patient's pursuits, that it cannot be adopted. A solid sound or catheter can only be used straight, or with its accustomed curve; a gum-elastic one can be made

to take any curve, and a soft bougie may be so managed, by bending it a little, about an inch from its point, to the right or the left, or otherwise, that the shaft may be level against the under part of the canal, whilst the point is directed against the upper.

When an elderly person is to be examined, who is known to have had stricture from his youth, there is no difference in the mode of proceeding, save that any stoppage of a small sized instrument, although it has gone beyond six inches and a half, must be viewed with great suspicion, as indicating the possibility of chronic enlargement of the prostate, the disease of elderly people, which gland should then be examined per rectum, and its enlargement, if any, ascertained. If the stricture admits of it, a large catheter will be found to pass easily, when properly borne against the upper part of the urethra, and its handle duly depressed, when the curve or stoppage of the smaller one will be satisfactorily explained. When the obstacle is further on, and at the neck of the bladder, it will be easily felt with due examination, and will be equally well known, by the sudden flow of urine on its entering the bladder, and by the peculiar sensation communicated to the hand at the moment.

If the elderly or middle aged man has attended but little to himself, and only knows that he has been some time suffering from a derangement about these parts, but what he cannot tell, and has no knowledge of any disease in earlier life, the surgeon must be cautious, even in his examination with a solid catheter, which is yet preferable to a soft bougie. There is, in most cases of disease of the prostate, some sympathetic irritation at the membranous part of the urethra, which will often offer considerable resistance to the passage of an instrument of a large size, and lead to the suspicion of stricture, after the same manner as irritation there, in early life, gives rise to a dilatable one. If a large catheter be forcibly used, the urethra will resist; but, unless there really be a stricture of a permanent kind, this irritable spot will be readily passed by gentleness and judgment in the management of the instrument, when the true nature of the complaint will be easily discovered. If there should be a permanent stricture, which is either unknown to, or only suspected by, the patient, the steady and regular obstruction to an instrument of a certain moderate size, whilst one a little less will readily pass through, and with the usual sensation of riding over an obstacle, will demonstrate its nature. Strictures in the urethra are prone to give rise to disease about the prostate, if not of the gland itself; but still, persons having the true chronic enlargement of the prostate, are not as commonly affected by obstruction in the anterior part of the urethra, as might be, *a priori*, supposed.

The disease being ascertained by the stricture, the means of cure are to be selected:—

they are three in number—by dilatation, by cauteries, by division, and, perhaps by a continuation of all these methods; and first of dilatation.

On the Cure of Stricture by Dilatation.

As an impassable stricture cannot be cured by dilatation until such time as a passage is obtained through it, sufficient to admit a small bougie, I shall for the present suppose that passage to exist. A bougie of a size that will pass without inconvenience, is to be introduced and allowed to remain for an hour, and if the bougie is a little conical, the stricture may not only be completely filled by it but moderately dilated. If the stricture be very irritable the soft bougie may be grasped and marked by it, and the same thing will occur if the bougie be too large and too strongly forced into it. If the bougie be rather too large at the point, it will not proceed on meeting with the stricture, although sometimes, by a gentle pressure for two or three minutes, the stricture will gradually yield and allow it to go through, but there is a probability that more irritation will follow this mode of proceeding than if a small one were first introduced for a quarter of an hour, and a larger one then made to take its place, which it will almost always readily do. This is in fact the principle on which dilatation should be conducted, and it will always be accomplished more safely and easily for the patient if done in that manner, for a larger bougie can always be introduced if it follows a small one, than can be got into the bladder without such a precursor. This is a fact that does not admit of a dispute. I never use the bougie as a mere dilating instrument oftener than every two days, and when the urethra is irritable, only every three and sometimes four days. Proceeding in this manner the stricture gradually yields, and a bougie, whether made of plaster or of silver, and as large as the orifice will permit to enter, will at last proceed through the whole passage without meeting with any obstacle, and it ought to be repeated at longer intervals, until this disposition for contraction seems to be removed; and where a stricture has been a permanent one, the patient should be taught the manner of doing it, so that he may use it once a week, then once a fortnight, and at last once a month, or quarter. In this manner I have made some most successful cures, even where the patient at the beginning of the treatment could scarcely pass his water; and there can be no doubt of its being the best when it is successful, for the inner membrane of the urethra is by it restored, as nearly as possible, to its former and natural state, and without any new formations; for, although the question of the reproduction of mucous membrane has been much agitated, and particularly by continental writers, there does not seem to be any sufficient reason for believing that a reproduced part is so perfectly like the original structure as to resemble it in

every respect, and particularly in its secreting properties.

It happens, however, most unfortunately, and in too many instances, that the orifice of the urethra will not admit an instrument of a size sufficient to dilate the constricted part to the natural dimensions of the urethra; and more unfortunately still, that if the orifice be dilated by division downwards, so as to admit a sound as large as the urethra will bear, still the diseased part cannot always be sufficiently dilated to remove its contracting propensities, and the patient, from neglect or otherwise, finds it impossible to keep it up; in other words, the disease is not cured, but only kept at bay, ready to return in a few weeks, or months at most, and to be quite as distressing as before. This method of proceeding will, however, cure a great number of persons who cannot be cured by the simple passing of the bougie without the dilatation; nevertheless, it will not cure all, and many persons do not like the enlargement of the orifice. It was formerly done, as I have already said, by stretching the orifice until it yielded, when it was torn generally downwards. This was fashionable then, but is not so now; and if you are obliged to do it, or think it right to do it where the orifice is naturally very small or vascular, you should do it by division with a small sharp knife; and if a short bougie, of a full size be introduced every morning for a few days, the orifice will remain patulous for the future. This practice succeeds, because the sides of the orifice possess their natural peculiar structure, and the inferior elastic part is quite cut through; but it does not succeed in a similar manner when the whole orifice has been eaten away by ulceration, and in healing, contracts almost to the smallest possible point, constituting a stricture at the orifice, and giving rise to very serious reflections, which bear very forcibly on the different modes of treatment. As far as I know from personal observation, or from written testimony, this sort of stricture is never cured by dilatation, although it may be relieved; and where a person has such a complaint, he should always carry about with him a short silver tube, to be introduced for an inch whenever he wishes to make water, in the same way, as I am told, the eunuchs, called black, from the extent of mutilation, do in the east. I have never seen, although I have read of a case of this kind having been cured by caustic, but I suspect it was only a temporary relief, followed by greater contraction; and the best means I am acquainted with, is to divide the orifice downwards, and prevent the wound contracting and closing during cicatrisation by the use of the bougie.

If you divide the orifice in this manner, and by this means are enabled to dilate the urethra to a greater extent, it does not always succeed in effecting a permanent cure; for although the solid silver sound will go through the orifice, it will not proceed along the urethra

without giving more pain than many people will submit to, and is therefore abandoned, the patient either changing his surgeon, or determining on putting up with the inconvenience. If this evil does not occur, another may, viz. the urethra becomes generally irritable or inflamed, an acute discharge is set up, and the bougie cannot be borne at all; or if this does not occur, it soon becomes apparent that this augmented dilatation is not sufficient to effect a permanent cure, and that a greater dilatation cannot be borne generally by the urethra; and, under these circumstances, attempts have been made to dilate the diseased part without dilating the whole, and even by this proceeding to avoid the preliminary step of dividing the orifice to obtain room for the admission of the larger instrument. My first attempt in this way, was by having a bulb made about an inch from the end of the instrument, which was small at its point, and gradually increased into a bulb, from which it again diminished to a proper sized shaft. This gave very much less pain than an instrument of the same size throughout, but I was soon satisfied that it was insufficient for all cases, and that in some a greater dilatation was necessary in order to effect a permanent cure, than could be made by this method. I then contrived an instrument with a bulb which opened by a piece of mechanism within it, worked by a screw in the handle, and I thought I must now certainly succeed, but this rather did too much, by producing irritation on the stricture and affecting the neighbouring parts, as the bladder, and even the testes, and proving to me that dilatation would not cure every kind of stricture. The history of the instrument is curious, inasmuch as it is the parent of most of those which have been made for various purposes connected with the bladder and urethra, and of the various improvements in the treatment of stone in the bladder which have been since introduced.

CONTRIBUTIONS ON MIDWIFERY.

BY THOMAS RADFORD,

Surgeon Extraordinary to the Manchester Lying-in Hospital, &c. &c.

NO. II.

On the Injury which the Head of the Child sometimes sustains in its passage through the Pelvis.

THE injuries which the head of the child sustains during its passage through the pelvis in protracted labours are very numerous. But that which is more particularly considered in the following remarks, is what is technically called the "mould shot head."

When the head enters a narrow pelvis,

and its occipito-frontal diameter corresponds with the oblique or the transverse of this cavity, and it is propelled through it by the unaided natural powers, an alteration in its figure is produced. The occipito-frontal diameter is considerably increased, whilst the conjugate is in an equal degree diminished. The same change in shape is observed in the head when it is long detained at the outlet of the pelvis, in consequence of rigidity of the soft parts. The brain bears this alteration in the figure of the cranium with comparative little inconvenience, because the pressure it sustains is parallel with the fibres of some of those parts which lie between the two hemispheres, and with the falx, which in its natural state supports this organ. The pressure is also less injurious, because it is applied upon the sides of the vessels, but not in such a degree as considerably to influence their calibres.

The figure of the "mould shot head" is very different from the one just described. It is very considerably increased from the base to the crown, and diminished in its occipito-frontal diameter. It does not take place in all cases of protracted labour, but only in such as are produced by a malposition of the foetal head. It sometimes occurs when pressure is artificially applied in the same direction.

When the head presents with its long diameter lying parallel with the short one of the superior aperture of the pelvis, the occiput may be situated towards the pubes, or towards the sacrum. In both cases the labour is slow and difficult, even if the pelvis is well-formed; but if, along with an unfavourable position, the pelvis be narrow, or if the head is larger than ordinary, the difficulties are considerably increased. In this presentation the alteration which takes place in the head is as follows:—a considerable diminution in the length of the occipito-frontal diameter is produced, in consequence of approximation between the frontal and occipital bones, the fontanelles become nearly obliterated, the parietal bones are forcibly separated, and the sagittal suture is wider and more prominent. The brain is pushed into this space, which is insufficient for its accommodation, its organisation is injured, and the child, when born, is either dead, or dies soon after birth.

Injuries of a similar character are sometimes met with, when the long forceps have been

used. This mischief will inevitably occur if the obstetrician has no regard to the kind of instrument he uses, or to the degree of pressure he applies. If the head is forcibly and rapidly dragged through the pelvis, regardless of the axis, instead of waiting for that moulding of the bones, which nature adopts when left to herself, effects of the most serious nature are produced upon both the mother and child. In all instrumental labours, when the head presents naturally, the pains, however trifling, if attended to, have a tendency to effect those salutary changes in the cranial bones whereby the delivery is accomplished more successfully. But if the instruments are brought into their full action, the tendency of these feeble efforts will be completely overcome.

Children, whose heads have suffered pressure in the direction of the occipito-frontal diameter, are frequently born dead, or they die soon after birth, unless the case is properly considered. They are unable to effectually commence the important function of respiration. The lungs are only partially filled with air by the convulsive sobs which take place. The action of the heart is not free; and if the pulsations in the funis continue, they are laboured and oppressed. The countenance is turgid, and of a livid colour, and the vessels of the conjunctiva are quite injected with blood. These symptoms fully prove, that the difficulty to commence respiration does not depend upon a mechanical obstruction from mucus in the trachea; but on the injury which the brain has suffered. This organ is in a state of apoplexy, sometimes depending on a very highly congested state of the blood vessels alone, sometimes on an effusion of blood, which takes place in different parts of the brain, and also varies in quantity. This opinion is corroborated by dissection, and the appearance discovered will be best understood by detailing a case or two.

CASE I.—I opened the head of a child which was born with the symptoms already mentioned, and lived twenty minutes. A considerable quantity of extravasated blood was found upon each hemisphere, between the pia mater and the tunica arachnoidea, and at the base of the brain upon the dura mater. The superficial vessels were universally gorged with blood. Those of the plexus choroidea were very turgid.

CASE II.—Upon opening a child born dead, after a protracted labour, in which the long forceps* had been applied, on account of distortion at the brim of the pelvis, I found a considerable quantity of coagulated blood upon the left hemisphere of the brain, and also upon and under the cerebellum. The structure of the brain was much softer than natural. The vessels upon the surface were very full. Upon opening the ventricles, a clot of a flattened shape was seen in the left. These serious effects are produced by the brain being compressed in a direction contrary to the course of the fibres of some of those parts which lie between the hemispheres, and also to the current of blood along the longitudinal sinus.

The pressure, applied to the fore and hind part of the head, has a tendency to change the relative situation of many parts of the brain. It forces one hemisphere from the other, which, if carried beyond a certain degree, will inevitably produce laceration of the coats of the veins, which pass to the longitudinal sinus; and this danger is increased by the great congestion which exists.

The practice to be adopted, is to bleed freely as soon as possible after the child is born. The funis ought to be divided before it has ceased to pulsate, as no blood can be obtained if this be neglected. If the pulsations in the vessels of the funis have ceased, two leeches must be applied to the temples.

If these means have not been adopted, convulsions generally ensue, as happened in the two following cases, the first of which I am indebted for the particulars to my esteemed friend and partner Mr. Hunt, and I shall cite it in his own words.

CASE III.—"In a case of difficult labour, which I attended last December, in conjunction with Mr. Greaves, one of the surgeons of the Lying-In Hospital, and which happened to a female suffering so much from contraction of the brim of the pelvis, as to induce the surgeon, who had attended at her preceding labour, to have recourse to embryotomy; the long forceps, with blades of equal length, were successfully employed, although very considerable difficulty was experienced in applying them. The child's head was not only

very much lengthened, but also distorted at the right parietal region, in consequence of the pressure occasioned by the combined action of the contracted pelvic bones and the blades of the forceps. The face was tumified and dark coloured, and respiration oppressed. It was thought desirable to allow some blood to flow from the funis, but as this was not divided until its pulsation had ceased, although no ligature was applied, no bleeding of the foetal portion followed. Next day the child continued to suffer from the state of the head, and had two convulsions; a leech was applied to each temple, gentle aperients ordered, and the child gradually recovered."

CASE IV.—I was requested by Mr. Dick to visit a poor woman in New Blakely-street, who was suffering from protracted labour, caused by contraction of the brim of the pelvis. The long forceps were applied, and the child delivered alive. A depression of considerable size was produced on the left parietal bone, from the pressure it had sustained from the promontory of the sacrum. The signs which the child manifested were those of apoplexy. The funis was divided, but no blood followed, as the pulsation had previously ceased. The child continued in the same state during the day, and in the evening was attacked with convulsions, which were frequent. Two leeches were applied to the temples, the bowels were opened, and the child recovered.

Foreign Medicine.

Angina following Measles.

In the *Gazette Médicale de Paris* of the 8th of this month there are some observations on gangrenous angina following measles. The author, Dr. David d'Ecneillé, prefaces his remarks by regretting that the attention of medical practitioners is not sufficiently directed to the subject of epidemic maladies, and he considers that this is the consequence of what he calls the centralisation of the study of medical sciences. They who are shut up in large towns are, in his opinion, less exposed to the causes which produce the different epidemics than those who dwell in the country; and consequently in the former places, where diseases nearly always present the same forms, the result of pathological observations is more

* The forceps used in this case, as well as in the one related before, were Dr. Hayton's.

usually confined in a small compass. He then proceeds to observe, that in no part of France have so many efforts to investigate these forms of disease been made, as in the departments of the Indre and of the Indre et Loire. In the year 1833, an epidemical form of the measles ravaged some of the districts of the two above-mentioned departments, and was, during the first few days of the fever, so mild in its symptoms, that medical treatment was not considered requisite. In a short time, however, the disease assumed a more complicated form, became much more serious, and presented symptoms more severe in adults than in children. It was constantly accompanied with pneumonia or pleuro-pneumonia, enteritis or gastro-enteritis, simple or pultaceous angina, rarely did it follow its natural course. The eruption frequently disappeared on the slightest exposure to cold, and then the angina became serious. At the termination of the eruption many of the patients had white-coloured scales upon the uvula or arch of the palate, which were generally arrested by the application to them of the hydrocyanic acid; this was not, however, always successful, for sometimes the disease continued in spite of its use, and the cases terminated in death, with all the phenomena which have given to this form of angina the name of gangrenous. Many of the cases of measles got well by the second or fourth day; and when slight diaphoretic drinks did not suffice for the cure, emetics of ipecacuanha often proved beneficial; if the state of the tongue and stomach did not allow of the administration of this medicine, a succession of one or two blisters applied to the arm often was of service, especially when there was coryza or ophthalmia.

From the consideration of this complaint, the author proceeds to speak of another epidemic which raged in the same part of the country. Scarcely had the cholera, the measles, the swellings about the ears, and the whooping-cough ceased to exercise their more or less fatal influence, when scarlatina, angina parotidea, and croup attacked a great number of children.

The affection of the parotids, either alone or accompanied with enlargement of the submaxillary and sublingual glands, was the constant prelude to the scarlatina, which was prevalent from the commencement of September. The patients cured of the glandular

enlargements were considered convalescent, when suddenly they were seized with the forerunning symptoms of scarlatina, and in twelve hours' time the eruption was generally complete; in other cases it was, however, longer in its development. The pains in the back part of the pharynx and difficulty of swallowing were very distressing, and greyish-coloured spots were observed on the former, which rapidly increased, and frequently caused the death of the patient in four or five days. Cauterisation seemed to arrest the disease most rapidly.

At the conclusion of the paper, Dr. David gives the following result of his observations on the different plans of treatment. Out of 58 cases of scarlatina which commenced in the parotids, 32 were bled in the commencement, and out of these one only terminated in death; out of 26 cases of long-existing angina parotidea, which were either leeches or bled with the lancet, six terminated in suppuration, petechiae, anasarca, or death. Of 18 patients who were attacked with croup, 10 were bled and carefully watched; one only died, the other eight were only seen during the last hours of their life, and all with the exception of one died.

Diseases resulting from Conception.

M. Velpeau has lately communicated to the Institute of France the result of his researches upon the maladies which conception produces. He divides them into the maladies of the foetus, of the cord, of the allantois, and of its canal, and regards them as the source of a great variety of monstrosities or of morbid productions.

The hydatids of the uterus, which occur in clusters, for example, are, according to M. Velpeau, a production from the external face of the chorion, a degeneration of the granulations, and of the villous surface which covers this membrane. Scirrhus and steatomatous tumours of the placenta result from the effusion of blood, in consequence of the rupture of the external surface of the placenta, so common during the three first months of pregnancy. This effusion sometimes happens to a great extent, and forming prominences upon the internal face of the membranes, which it raises, often causing miscarriage; sometimes, however, its growth is suddenly arrested, and then it permits of the pregnancy

proceeding to its completion.—*Revue Médicale*.

TRANSLATION OF M. ALIBERT ON
THE DISEASES OF THE SKIN.

BY SAMUEL PLUMBE, M.R.C.S.

*Late Senior Surgeon to the Royal Infirmary
for Children, &c.*

We resume the translation of M. Alibert after a lapse, which has created an impatience on the part of many of our readers, but with the hope that we shall now be able better to effect our object, inasmuch as we have now on our table the latest complete edition of the letter-press, and the whole of the engravings, which have been completed, before us. M. A. having expressed a very reasonable dissatisfaction on some points, regarding the translations before published, we shall now give him, as well as our readers, the pleasure of reading a very correct (at least as far as our humble abilities go) translation of his "grand work."

M. Alibert is yet an enthusiastic student, as regards diseases of the skin, and it is evident, from the spirit pervading every line of his writings, that though half a century has passed over his head, since his attention was first directed to the subject, he has lost none of the ardour of youth in following it up. It is evident, also, from his writings, that he is a good and amiable man, and that the interest of his fellow-creatures is his greatest study. He plainly perceives, that best to serve that interest in his character as a physician he should direct his exertions towards the improvement of medical science, and particularly that branch of it which circumstances have given him opportunities of observation of, not to be obtained by more than a few. His juniors may be content to follow in his steps, and be well satisfied by picking up from time to time a grain from the chaff he, in his long life of practical experience, habitually sifted, and which escaped his observation; but they hardly find these grains, sow them as they will, productive of any thing deteriorating Mr. A's. high character as the first of French dermatologists.

Still, with the obligation before us of rendering M. Alibert to our readers as near as possible, according to his own meaning, we are compelled to look seriously at the space necessary to do justice to ourselves and to

him at the same time, and we must therefore say, as indeed we did at the commencement of the undertaking, that we will look *first* to our contract to our readers to give all which is new and established, as valuable, in the writings of our author, and that the description of the disease, the pathology, etiology, and method of treatment shall follow with the utmost regularity.

M. Alibert has invented a new form of illustration of the classes of cutaneous diseases. He has constructed an "Arbre des Dermatoses,"—a tree, the branches of which are twelve in number. We need not say more to excuse us from copying it, and handing it in our pages to our readers, than that the

First branch has	. 47 sprouts,
Second branch	. 28 sprouts,
Third branch	. 14 sprouts,
Fourth branch	. 21 sprouts,
Fifth branch	. 10 sprouts,
Sixth branch	. 14 sprouts.

134 varieties of disease
on one side.

On the other

First branch has	. 29 sprouts,
Second branch	. 7 sprouts,
Third branch	. 7 sprouts,
Fourth branch	. 8 sprouts,
Fifth branch	. 6 sprouts,
Sixth branch	. 8 sprouts.

65—199 total.

This *denouement* will hardly, we think, induce our readers to purchase M. Alibert's book in this country, because the arrangement altogether, the multiplied divisions and subdivisions are such, that, on the very first view, none but a disciple of M. Alibert could tolerate, much less study, them.

To return, however, to our original object, namely, a translation of the new edition of the work before us, M. Alibert commences with "Erythema," which we take the liberty to interpret "Inflammation of the Cutis."

Of this he names seven kinds—

1. The spontaneous,
2. The epidemic,
3. The endermic,
4. Intertrigo,
5. The paratrine (from pressure),
6. Chilblains,

an affection, by the way, as well known to

involve the cellular tissue beneath the cutis as erysipelas, and

7. Inflammation from burning.

Erysipelas itself he has very properly estimated, in giving it no place among diseases so comparatively trivial.

The *spontaneous* form of erythema, he says, is marked by spots or spaces of different shades of redness, as if the parts had been exposed to the rays of a scorching sun. The backs of the hands, the face, the chest and lower extremities, and other parts of the body, simultaneously or alternately, are affected, always having distinct spaces of healthy natural appearance of the skin intervening. This form of disease is accompanied with slight sensations of pricking and irritation, similar to those produced by stimulating applications. A tingling and feeling of stiffness, such as a needle produces on pricking the skin, or the sting of a hornet, &c., next follow, and then symptoms of fever supervene. The conjunctiva becomes red in the neighbourhood of the carunculae lachrymales. There is severe headach, and the heat of the skin prevents sleep.

When the affection has attained its highest point, the skin is swollen, and tender, and shining. When it begins to subside it assumes a blue, violet, or yellow colour. The cuticle exfoliates, but in a short time it regains its normal state. It is sometimes of a chronic character, sometimes more active.

The *epidemic* erythema, it appears, first attracted the attention of M. Alibert in 1828, when many patients of each sex were received at the hospital of St. Louis from different parts of Paris. The hands and feet of these were affected with swelling, accompanied with a sense of formication or pricking, and tingling, throbbing, burning, &c. It appeared in the Infirmary of Marie Theresa, in the Hôpital de la Charité, and the Hôtel Dieu in the upper stories, with symptoms more or less severe. MM. Miguel, Chomel, Cayol, Récamier, Bally, Chardon, and others, have published remarks on it as it passed under their observation, and of course, in an institution particularly appropriated to the treatment of diseases of the skin, we have not been unmindful of it ourselves. Successive desquamations of cuticle take place in most parts of the body, and particularly about the joints. Our means of observation were more extensive in St. Louis than elsewhere, for the reasons before men-

tioned. Many of the patients here were found to have vesicles on the extremities, containing a reddish serous fluid. These discharged their contents, and the cuticle exfoliated, leaving dry scales and scurf, which gradually disappeared. On the hands and other parts of the extremities they were thin, but on the feet somewhat thicker, and often very hard and thick indeed. In one case, of a pedlar, the heels were corned and hard as marble, and the lower part of the legs were encased as if in a boot.

The patients presented, besides the appearances described, circumscribed purple, or red patches on the fore-arms, hands, thighs, legs, and feet. A sooty black colour of the integuments of the abdomen, chest, arm-pits, &c., also evinced itself in the greater number of cases. One female particularly, whose breast was affected, had the nipple covered by this thickened and black cuticle, which ultimately separated like the cup of the acorn from the fruit. Many were so discoloured as to resemble chimney-sweepers, and when scratching off the discoloured exfoliating cuticle, and exposing the part beneath was resorted to, it was found covered by a substance like a dried earthy or farinaceous powder. The surface of the skin is in some cases found to be dry and harsh, as if it had been exposed to the heat of an oven.

Numbness of the feet, rigidity of the skin, inflicting much pain in walking, and much inconvenience in moving the fingers were the sequelæ.

This singular epidemic occasionally was accompanied with symptoms of a more serious character; vomiting, diarrhoea, strangury, convulsive and suffocating cough, blindness, &c.

Endemic Erythema.—This is the *pellagea* of Lombardy.

It is, says M. Alibert, a chronic disease of the skin, which shews itself usually towards the end of winter or beginning of spring. It attacks exclusively the peasantry, who work exposed to the rays of the sun, and who spend the best part of their lives in fatigue and misery. It is reproduced at the same period from year to year, through the life of the sufferer if he continue exposed to the cause of it. It was thought endemic where it was first noticed among the Milanese, but it is now known to extend itself wherever the same causes found to exist. Piedmont is not free fr

and cases have been seen at Vienna, and one individual, affected with it, has been seen by M. Alibert in Paris. The manner, in which this disease shows itself, is as follows:—towards the end of February or the beginning of March, when the peasants resume their labours in the fields, itching more or less violent is experienced by some of them about the fore-part of the neck and chest. The feet, the hands, and face are especially affected, the skin reddens, and a slight erythema shows itself, followed by desquamation about the ninth or tenth day. If, however, the skin is protected by any covering from the heat of the sun, no mischief arises; the backs of the hands, then necessarily remaining exposed, are the only parts on which it is seen, a severe smarting is felt, blisters containing a yellow fluid are formed, never becoming afterwards healthy in appearance, but breaking are succeeded by a blackish adherent crust, which is a long time in separating, and is renewed at intervals. However slight the attack, it scarcely ever disappears before the end of autumn. As winter comes on, the skin approaches to a healthy character, but remains dry and harsh, and shining as if covered with varnish. The following year the disease reappears, and goes through the course described over again. There is a variety designated "*la salsedine*," not so much dependent on the seasons of the year, and irregular as to the period of its appearance. A saltish taste in the mouth commonly experienced gives it this name; it is felt most in the morning rising. An acid discharge from the nose accompanies it. Diarrhoea, pale and foetid urine, and an offensive perspiration follow. Loler says that the hair assumes a red and singed appearance, and drops off. Paintings and cramps take place, particularly in the muscles of the lower jaw. The persons affected sometimes have so little command over the muscles of volition, that when they attempt to walk they cannot turn, but proceed in a direct line, and endeavour to support themselves against any object in their way; others remain motionless, excessive tremor is the distinguishing feature of other cases; these and others ultimately become idiots, or at least insane, and a disposition to destroy themselves by drowning is supposed by some to be caused by the burning heat of the skin belonging to the disease.

The fourth species is the *E. Intertrigo*, or

chafing between the legs. It takes place in corpulent persons not of cleanly habits, and in young children whose linen is not sufficiently often changed. If acrid, or even healthy urine is suffered to moisten the linen for any length of time, this affection is the consequence. Thus those who suffer from paralysis of the bladder can hardly be protected from it.

E. Paravrine; i. e. inflammation from pressure. M. Alibert has two kinds; that arising in the palm of the hand in labour with hard implements, and that so often seen on the coccyx in bed-ridden patients.

Itching and heat in the palm, and chronic inflammation, thickening of the cutis, and sometimes adhesion of the subcutaneous structure to the tendons of the flexor muscles take place. In such a case some alarm may be reasonably felt.

The skin over the coccyx often becomes inflamed in bed-ridden patients. It follows where patients have suffered from typhus, scurvy, and other diseases, wears an aggravated form in the more serious of these diseases. It often terminates in gangrene.

E. Pemio, or inflammation from chilblains.

This is a disease which makes its appearance on the setting in of winter, and disappears as the weather gets warmer. Children, who are most subject to it, experience itching, and tingling. The poor exposed to cold show themselves first with sanious ill-conditioned sores, surrounded by thickening of the integuments, which become of a blue colour. Some writers think that the bone is occasionally involved.

E. par adustion; or the inflammation produced by burns. The effects of fire on living substances are totally different from those on dead or inert matter. M. Dupuytren, to show more methodically the phenomena of this aniduct, has adopted a division into six degrees. In the first or slightest, the skin is merely reddened. 2. It is blistered. 3. The cutis is involved, and it becomes excoriated. 4. An eschar or slough of the surface takes place. 5. The inflammation finishes by destroying the cellular tissue, and separating it from the bone. 6. The injured part is in the first instance, and at once, burnt to a cinder.

These different states every one will understand. In one individual they can never all be seen together. An event, however, oc-

curred in Paris, in 1810, which gave French surgeons an opportunity of witnessing them all at the same period, under the following afflicting circumstances. A fête was given in this year by a foreign ambassador to the Emperor Napoleon. An immense assemblage took place; the rooms of the palace, all thrown open to dancers, were discovered suddenly to be on fire. Six hundred persons were surrounded by the fire. Perhaps there was never a greater number of persons assembled, where terror was so powerful as to prevent flight. They were surrounded by fire; every thing favoured its activity. The varnished papers, the multiplicity of light, the light and flowing garments of the females, all contributed to favour the fatal element.

The slightest as well as the worst cases of burns were upon this occasion furnished to the French school for attention and observation. Never heart had so much to tremble at, never science so much to learn.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, February 22nd, 1834.

Mr. PERTIGREW in the Chair.

Torsion of Arteries.

THE usual business of the evening having been transacted,

Mr. Costello proceeded to perform the operation of torsion on the femoral and carotid arteries of a dog. He was assisted by Mr. Quain and Mr. Dobson. He laid bare the vessel, and then called the attention of the surrounders to the fact that there was a distinct pulsation, noticing this in refutation of the statement of Dr. Parry, that arterial trunks when exposed do not pulsate. Two pairs of forceps were then applied to the vessel, about three or four lines apart, and its coats were divided between them; the separated portions were then dexterously twisted several times, and on removing the forceps, little or no hæmorrhage ensued.

Objections were raised to this operation by Mr. King and Mr. Greenwood, the latter of which gentlemen enumerated the different processes following the application of a ligature.

Mr. Costello then made several observations

in answer to these objections, and gave a review of the remarks which he had made on the subject on a preceding evening, after which the Society separated.

MEDICAL SOCIETY OF LONDON.

Monday, February 24th, 1834.

W. KINGDON, Esq., President, in the Chair.

Empyema—Diseases of the Lungs simulating Hydrocephalus—Calomel in Pneumonia.

THE preliminary business of the evening having been completed,

Dr. Whiting proceeded to relate the case of an infant, ætat. 6 months, in which the breathing was performed with difficulty, the face was slightly tinged with blueness, and the left side of the thorax was deformed, there being a projection of the ribs of more than half an inch on that side; the pulsation of the heart was felt in the right cavity, and in the epigastrium; there was no respiratory sound in the lower part of the chest on the affected side; at the upper part, however, puerile respiration was evident; the child could lie with the greatest ease on this side, and it appeared from the statement of the parents, that there had been some pulmonary ailment previously, but of what nature did not appear. From the train of symptoms which were observed, it was considered that there was deposition of fluid into the cavity of the pleura, and that it was a proper case for the performance of paracentesis; this was however delayed, nothing was given to the child but the breast milk, and under this absence of all medicines it continued to improve till last Wednesday, when it was observed to be at a stand still; small doses of digitalis and blue pill were then given, and under this treatment the child amended, and is now in a fair way for recovery. He thought, judging from the sequel of this case and other instances, that too frequent use of the trocar was often made, as it would appear that it was best to watch the progress of the complaint.

Mr. Kingdon said his attention had been directed to a corresponding case some time since; a child was seen by him twenty-four hours before its death, and appeared to be dying from hydrocephalus. The disease had been considered as an affection of the lungs,

and the surgeon who attended the case thought that the child had died from this affection. The body was examined, and both hydrocephalic appearances and empyema on one side of the thorax were found; probably if the disease in the head had not supervened, the child would have recovered; he coincided with Dr. Whiting in his opinion with regard to the too frequent use of the trocar.

Mr. Dendy had attended a child, set. three months, in whom there was pain in the left side, dyspnoea, and inflammatory symptoms; proper antiphlogistic treatment was adopted, and for some time the child improved. On the fifth or sixth day the symptoms were aggravated, the breathing was laboured, and there was found tumefaction at one part of the chest, projecting between the ribs; respiration was indistinct at the lower part of the thorax on this side, but there was no metallic sound. In the presence of Mr. Callaway an oblique puncture was made in the tumour, when about two ounces of a limpid ichorous fluid escaped. In five or six hours the whole of the symptoms were much alleviated; the child went on well for some time, but on the sixth morning it died. It was evident that there was a relapse of the disease, since the child was getting better rapidly. No post-mortem examination was permitted; but the presence of fluid in the chest was, he thought, sufficiently well marked. In answer to a question, Mr. Dendy said that the tumour pointed externally, and was as large as a goose's egg, was situated near the apex of the heart, and had penetrated through the intercostal muscles; no external marks of inflammation were observed.

Mr. Kingdon said the amelioration in the symptoms certainly led to the supposition that there was no fluid at that time in the thorax, but it was possible that it was then making its way externally.

Dr. Whiting did not think that this was a case of empyema, but was probably an abscess formed internally, making its way to the parietes of the thorax. He did not think that openings into abscesses made at an early period were attended with benefit, as great constitutional irritation was thereby caused. In one instance he had found the abscess bursting internally into the bronchial tubes, and allowing of the escape of the pus mixed with blood by the mouth. It was probable

. Dendy's case the abscess was

formed either in the lungs or in the pleura, which was adherent.

The subject having dropped,

Mr. Kingdon informed the Society that an essay on the properties and uses of the *labelia inflata* had just been laid before him by Mr. Robarts; but, as a great portion of the evening had elapsed, he thought it better that so important a paper should be deferred until some future occasion, in which opinion the Society agreed.

Mr. Headland wished to draw their attention to the subject of pulmonary disease simulating the symptoms of disease of the brain; this was well known to all as occurring frequently, and rendering the nature of the disease, at least in young children, exceedingly ambiguous. He was also desirous of ascertaining the views of Dr. Whiting (to whom all the Society were indebted for the many important remarks which he had made) on this subject, as to the efficacy of calomel in cases of pneumonia.

Dr. Whiting said he would wish to delay what he had to say on this subject till later in the evening, as many other members might be desirous to address the Society, and as he felt that he had already trespassed too much on their time.

Mr. Kingdon related an instance of pulmonary disease in his own family, where the administration of calomel had been used with perfect success, after other means had failed in arresting the complaint.

Mr. Stevens had met with a case precisely similar to those alluded to by Mr. Headland. The symptoms were all situated in the head, the thorax being entirely free from all appearance of disease; examination however proved that, although there was a slight degree of vascularity in the vessels situated at the base of the brain, still the principal traces of disease were found in the thorax. The lungs were tinged and vascular, the cells being filled with a frothy fluid; the child had had epileptic fits, and it might have so occurred, that the violent efforts during the paroxysms might have caused this appearance, as it did not altogether resemble inflammation. He was accustomed generally to give emetics previous to bleeding; and he had found that by this mode of practice the difficulty of breathing, and all the inflammatory symptoms were sooner relieved.

Mr. Proctor did not coincide with the last speaker in his opinion with regard to the safety of exhibiting emetics in the first instance; he however thought they might prove good auxiliaries. Local bleeding was, in his opinion, necessary in these acute forms of disease; as regarded calomel, he had used it many years since, but had not found it to prove such a specific as Dr. Whiting had on a former evening represented it.

Dr. Whiting, after making some remarks on the subject of auscultation, the use of which he considered as of very great importance in forming our opinions on diseases of the chest, said, with respect to the question of giving calomel in pneumonia, it was only in inflammations which did not partake of a specific nature, that he had found such decided benefit from its use; it was by the giving small doses and at long intervals that it did good, but the constant exhibition of a grain each hour scarcely ever failed to produce much and rapid relief. He related a case bearing upon this subject, when, the time for terminating the discussion having arrived, the meeting separated.

**MEDICO-BOTANICAL SOCIETY OF
LONDON.**

Tuesday, February 25th, 1834.

Dr. CHOWNE in the Chair.

On the Dietetic and Medicinal use of Tea.

Dr. RYAN delivered a lecture on the dietetic and medicinal use of tea, in which he cited a great number of writers, who praised it in the highest terms, and many who condemned it as a fertile cause of diseases. The majority of the authorities quoted were in favour of the salutiferous properties of the article. He contended that its effects were modified by age, sex, constitution, and habit. He expatiated on the superiority and safety of black in preference to green tea. He adduced the evidence of the great mass of society in favour of the exhilarating effects produced by this beverage on most persons, and on the exaltation of the intellectual and physical powers, and the extraordinary effect it possessed of causing vigilance or want of sleep. He proved that tea was conducive to health when used in moderation, but was highly injurious when taken too strong, or used in excess, without a proper quantity of solid aliment. He detailed

the effects of it upon himself under different conditions, when fatigued, or when taken on an empty stomach. He quoted Short, Petensen, Murray, the author of *App. Medicaminum*, Whytt, Beddoes, Smith, Lettsom, and many others, on the deleterious effects of tea. He also cited several who considered the different teas tonic, excitant, stimulant, and afterwards narcotic, sedative, diuretic, and diaphoretic. He illustrated, by numerous cases, its deleterious effects in inducing nervousness, lowness of spirits, tremors of the limbs, indigestion, disordered action of the heart, laborious respiration, faintness, change of temper. He alluded to the paper of Mr. Cole, read at the late meeting of the Medical Society; and after speaking in high terms of that gentleman's observations on the use of tea and coffee for fifteen years, could not agree with him, that these were the exciting cause of organic diseases of the heart, which were now so common. He mentioned a variety of causes of dyspepsia and functional disorder of the heart, and contended that organic diseases of that organ were not more common at present than they had always been; but that they had passed unnoticed until the discovery of the stethoscope, and the application of auscultation. He fully agreed with Mr. Cole, that dyspepsia, hypochondriasis, and various anomalous nervous affections, were greatly benefited and often relieved by the sufferers discontinuing the use of tea for some short time; but many persons so affected derived great relief from a moderate use of tea, and often gave it up with great reluctance. He then described the effects of tea, when taken without and with solid aliment, when the digestive organs were disordered, and in a state of health, and as modified by the addition of milk and sugar. He concluded by observing, that the good effects of tea experienced by the bulk of mankind, overbalanced the effects caused by its abuse in individual cases. He argued that the introduction of tea had greatly improved civilisation, by preventing intemperance, and replacing it by sobriety, by diminishing expense and debauchery. He stated that various attempts had been made to introduce infusions of indigenous plants in place of tea, but all had failed, and must fail. In recapitulation, he remarked, that a moderate use of black or bohea tea, as employed in this country, was highly conducive to health, but that green tea

was highly injurious. Dr. Ryan said, that he had confined himself to the good and bad effects of tea, and avoided details, which would occupy more time than the regulations of the Society would permit. He was anxious to derive farther information from many gentlemen present, who had been in China, more particularly with respect to the practice in that country of using tea, as he believed it was seldom employed sooner than a year or two after its preparation.

The Chairman observed, that the subject, so ably treated by the learned Professor, was one of great interest, and the Society would be happy to hear observations from visitors or members.

Dr. Sigmond then addressed the meeting, and expatiated at great length on the noxious and innoxious properties of tea. He described its effects on the animal economy, at different hours of the day, and in different states of the system. His observations were listened to with great attention, and elicited applause.

Mr. Judd mentioned a curious fact, which was, that when he was in Dublin, he knew dropsy cured by an infusion of green tea, made from the rejected leaves of the article, used by the nurse of the hospital. A patient was twice relieved with this remedy. He knew 1600 individuals who took coffee, yet paralysis was very common amongst them.

A gentleman observed, that, in reply to a question put by the learned Professor, as to the length of time the Chinese kept tea before they used it, he that day received a Canton newspaper, in which it was stated, that the period was from a year to a year and a half.

Mr. Smyly said that he was six times in China, and could speak from personal observation. He said the Chinese took tea, not as a meal, as we did, but during the whole day. It was the custom to present a visitor, first with a pipe, and then with a cup of tea. He bore testimony to the salubrity of the beverage, for the Chinese were a robust people, and lived to an old age.

Dr. Negri gave a minute account of the effects of tea upon himself, which corroborated that of his friend, Dr. Ryan's.

Mr. Pettigrew observed, that he knew a person who could not bear tea of a morning, but took it freely of an evening; and another who found it a preventive of intoxication.

It was then announced, that Mr. Everett,

the Professor of Chemistry, would lecture on tea at the next meeting.

THE

London Medical & Surgical Journal.

Saturday, March 1, 1834.

POWER TO CONFER MEDICAL DEGREES IN LONDON.

THERE is not a capital in Europe without its Universities, except that which exceeds them all, and all that history records, in extent and population. London contains about a million and a half of inhabitants, a large fraction of the population of Great Britain;—and yet, strange to say, the Government, in all its vicissitudes of courtiers and patriots, has never troubled itself with the thought of providing for the convenience of the first city in the world, by establishing a Chartered University within it.

Public instruction, the first care of every German Prince, (including his Majesty in his Hanoverian dominions,) has never been an object of Cabinet solicitude in England. "In pious times," the munificence of her sovereigns founded some Colleges; the wealth of a few of her mitred clergy was liberally devoted to the same purpose; and the death-bed generosity of many private individuals has provided funds for the maintenance of public schools, almost sufficient, under proper management, for the purposes of elementary education. But all these establishments of by-gone days, partake of the times in which they date their origin;—and, without questioning the wisdom of our ancestors, we may be allowed to judge, as they did, for ourselves in pronouncing the *letter* of their donations unsuited to the nineteenth century; nor should we apprehend grieving their spirit, by adapting their liberality to the wants of the age we live in.

Since the revolution, prelates have been too busy in erecting and aggrandising families, and successful adventurers in trade too full of the pomps and the vanities of the world to which wealth is the passport, to add to the stock for public education;—since that period, also, the personal influence of sovereigns has passed into the hands of ministers, and their tenure has been heretofore too insecure, too much dependent upon party principles and family connexions, to induce any Government to add to its difficulties the gratuitous task of legislating for public education.

We trust we have the good fortune to live in a new era, when the instruction of the people will be felt as the great duty of the Government. The subject is known to have occupied the Lord Chancellor's attention long before his Lordship's elevation to the influence of office;—and, promoted as he was—supported as he is, by a power beyond the intrigues of party, we have a confident assurance the Government of which he is so distinguished a member, will not shrink from the labours of revising and supplying the defects in the means of public education. Already are we indebted to his activity for the establishment of two great schools in the metropolis. The London University is the growth of his private interest; and the King's College, with its aristocratic subscribers, would never have existed without the stimulus of his exertions.

Neither of these schools at present possess a charter. As both of them, however, contain schools of medicine, it is not improbable they are looking forward to the possession of the power of conferring medical degrees, a power, which, it is admitted on all hands, should be vested in some body in the metropolis. In the present inquiry into medical education,

the proper depository of this power will, of course, occupy much attention.

It seems to us an indisputable principle, that the power of teaching should be left open to every possible competition, consistent with the proper qualification of the teachers. Some would have the examination of the candidate for a medical degree every thing, and would disregard the quality of his teachers, provided the candidate passes the requisite examination. In other words, they would overthrow what is called the certificate system. Agreeing in the paramount importance of the examination test, we cannot dispense with some inquiry into the student's sources of information;—and even, for the sake of the student, as a guide in his professional studies, certain recognised teachers should be appointed, who, of course, should possess qualifications, both professional and collateral, beyond the requisites for admission to practice. The nature and amount of these qualifications, and the mode in which they should be tested, are matters of interesting inquiry. The *Retired Practitioner*, whilst he admits the general practitioner, or doctor (as he would have him called) who has not had, upon obtaining his degree, the requisite increased knowledge for the rank of a teacher, (or a Fellow of the Royal College of Medicine, according to his nomenclature,) to offer himself, after some years' application to practice, as a candidate for this, the highest rank in the profession in his system,—allows others at once to take precedence, upon undergoing the necessary examination. It may be suggested whether it would not be more advisable, that none should be admitted to the honour of teaching without the experience of some years' practice in their profession.—However, whether the rank of teachers is to be recognised as the

highest rank of the profession or not, it is quite clear, that no real competition can subsist amongst lecturers, if the power of conferring degrees were bestowed exclusively upon any body having a school of medicine;—such a body would, of necessity, monopolise all students, from the real or supposed advantage of a connexion with those who were ultimately to examine all candidates; and that, without any reference to the merits of its Professors. For this reason it is advisable that a NEW board, distinct from any particular medical school, should be established in London for the purpose of conferring medical degrees; and that all the recognised Lecturers should be members of it; and that the Examiners should be chosen by ballot out of that class. The details of its management may be matter for further inquiry. But in the general principles here stated,—in the necessity of having in London, and, perhaps, at some other points of the United Kingdom, besides Dublin and Edinburgh, a body or faculty with power to confer medical degrees,—in the necessity of isolating this body from any one school of medicine, in order to secure a fair competition amongst qualified Lecturers; in these essential particulars we anticipate the concurrence of the unprejudiced part of the profession.

The pertinacious bigotry of the University of Cambridge has been brought, we are glad to observe, before Parliament. An hon. member has given notice of a motion for returns upon the religious tests exacted at the University. It matters little, however, to the profession what course the Universities in their repentance may be desirous to pursue. The highest honours of medicine can be no longer at their award; and the utmost value to be given to a degree in arts can only be

to save its possessor from a rigorous examination in such parts of academical study as may be required, and justly required, from any particular class of the profession. Besides, it is very probable that the power of conferring degrees in arts will be given to one or both of the great London schools.

PROFESSIONAL MEETINGS.

In this

“Sullen interval of war,”

we would not have our brethren in the country relax their efforts, or think that their co-operation in petitioning the legislature is unnecessary because a Parliamentary Committee is at this moment sitting. It is desirable to impress upon the legislature the necessity of reforming the intolerable abuses to which we are exposed; and to rouse the interest—not of the Committee, on which there are some ardent friends to the profession, but of the House of Commons. Nor is it to the lower House only we should direct our attentions. There is another place more swampy in its nature, over which it often requires some broad contrivance like snow-shoes to pass without sinking. The House of Lords, we are assured, will be dosed by the worthies of Pall Mall East; and, perhaps, at this moment, while the whole profession is confidently awaiting the decision of the Committee, in sober certainty that the legislature will act upon it, our antagonists are chuckling at the *possible* defeat of all our hopes in the upper House. Let not, therefore, the profession think that there is nothing further to be done; but, to ensure success, let them still act as if they had yet to make their first step. We have observed with gratification the alertness of the profession in the north of Ireland; and we implore our fellow-sufferers in

this country to imitate the example of the profession at Liverpool.

Since our last number, some members have been added to the Committee; which is understood to be still engaged in receiving documentary evidence.

French Hospital Reports.

HÔTEL DIEU.

Paralysis of the Organs of Sight, Smelling, and Hearing on the right side of the Face.

DURING one of the three days of the revolution of 1830, a man, named Godin, received a ball on the left side of the nose, which, having traversed the face in an oblique direction, made its appearance beneath the integuments, a little below the mastoid process on the right side of the neck. The opening, where the ball had penetrated, was perfectly round, corresponded in size to an ordinary bullet, and was situated precisely upon the level of the lachrymal duct, about two lines from the tendons of the orbicularis oculi. An incision was made upon the tumour, beneath the mastoid process, and the bullet, a little flattened on one side, was extracted without any difficulty. Some febrile disturbance of the system followed, which however soon disappeared; and then it was perceived that the whole of the right side of the face, along which the ball had passed, was completely paralysed, sensation and motion were quite abolished, there was a marked distortion of the mouth, which was drawn up to the left side, and was particularly evident when he attempted either to laugh or speak; the eye, upon the same side, had ceased to be at all sensible to even the most vivid light, but there was however no apparent alteration in its structure, and the pupil still preserved its contractility. On this side of the face the sense, both of smelling and hearing, was completely destroyed, whilst, on the left, these organs still preserved their sensibility.

Fifteen days after the wound hæmorrhage took place at the back of the fauces, and the patient, in a short time, lost upwards of a pound of a blood; the place from which the blood escaped could not be found, but as it chanced this was of no importance, for the hæmorrhage ceased spontaneously, and did not

return. This patient left the hospital without any improvement in the paralytic symptoms, and at the end of six months still continued in the same state.

Inflammation of the Uterus and Ovaries.—Acute Peritonitis.—Death.—Autopsy.

In No. 3. Ward is a patient, who has suffered some time from chronic affection of the uterus and ovaries. In the hypogastric region there is a tumour, which extends even as high as the umbilicus, and in the left iliac fossa there is another of smaller size. She has œdema of the left lower extremity, and suffers much from violent pains in this leg, and irregular attacks of shiverings.

Jan. 30th. The pulse this morning is 120, and all the symptoms seem to announce the existence of suppuration in one of the abdominal tumours, most probably in the left ovary, the œdema and the pains in the left leg are manifestly caused by the pressure of the tumours on the vessels and crural nerve.

Since the last report this patient has been seized with acute peritonitis. The abdomen became swollen and extremely painful, nausea and vomiting occurred, the pulse rose to 160, and could scarcely be felt; mercurial frictions were applied to the abdomen, and blisters were placed upon the thighs. The prognosis, given by M. Chomel a few days previously, proved correct, for in three days the case terminated fatally.

Autopsy.—A sero-purulent effusion was found in the cavity of the peritoneum. The uterus, ovaries, and cæcum had contracted old adhesions, and the walls of the first viscus were much thickened, and its tissue was of a grey colour; the two ovaries were in a state of suppuration; the left iliac bone was denuded, and in the fossa of this side there was purulent effusion, which surrounded the psoas and iliacus internus muscle. In the stomach the mucous membrane was found in a complete state of ramollissement.

HÔPITAL MILITAIRE DE STRASBOURG.

Venereal Ulcers caused by the application of Leeches.—Amputation of the Penis.—Retention of Urine.—Puncture of the Bladder.

— Desret, æt. 22, was admitted into the hospital with a venereal ulcer at the base of the glans penis, complicated with phymosis,

for which the application of leeches was judged advisable. Six were applied to the penis, but all the bites terminated in ulcerous wounds, which rapidly increased in size; the ulcer of the glans at the same time making rapid progress. Incisions were made in the prepuce, and afterwards it was excised, but the wounds resulting from both of these operations ulcerated. After trying in vain many cauterisations and different plans of treatment, M. Béclard decided upon amputating the penis near to the pelvis. It chanced, in the operation, that the introduction of the catheter was delayed until after the application of the ligatures, and it then became impossible to discover the opening of the urethra, in consequence of the retraction of the stump. It became, therefore, necessary to wait until the passage of urine should discover the aperture. At length a desire to micturate was felt, but in vain did the patient endeavour to evacuate his bladder, for not one drop escaped. On the succeeding day M. Béclard, fearing that he had tied the urethra, undid all the ligatures, but still the desired opening escaped observation, and relief was only afforded by puncturing the bladder through the rectum. In consequence of the imprudence of the patient the canula escaped in a few days, and recourse was had, this time, to the puncture above the pubis, because of the swelling of the prostate gland. At the end of eight days, the urethra still being invisible, and the urine not escaping by its natural exit, the operation of cutting down upon the canal was performed with success. Inflammatory attacks several times made their appearance, and rendered the puncture above the pelvis each time indispensable. The urine still continued, however, to flow through the opening made anterior to the prostate. At the end of nine months this man was attacked with confluent small-pox, and died from suffocation caused by suppuration of the interior of the larynx.

Strangulated Entero-Epiplocele Crural Hernia—Double Incision at the Crural Ring necessary to relieve the Stricture—Cure.

M. G., *etat.* 58, a woman of lofty stature, and formerly of a robust constitution, has suf-

fered for a long time from derangement of the digestive organs, chronic bronchitis, and crural hernia of the left side, for which latter complaint she has constantly worn a truss. On the 5th of April the hernia became strangulated, and as all the plans adapted for its reduction failed, M. Goyrand determined not to delay the operation. The tumour was as large as a pullet's egg, hard and very painful. She complained of hiccups, and constantly vomited stercoraceous matter. An oblique incision downwards and inwards was made over the tumour, and the layers were successively opened; in the sac was found a portion of epiploon folded on itself about two inches and a half wide, and three long; below this was a knuckle of large intestine of a dark brown colour. The operator passed a bistoury under the falciform ring, and made an incision of two or three inches in length at the crural arch where the stricture was situated; this was sufficient to allow of the reduction of the intestinal portion of the hernia, but a further enlargement of the crural ring was necessary to effect the return of the omentum. This incision was made upon Gimbernat's ligament, and sufficed for the easy return of the protruding portion. The convalescence of this patient was long retarded by inflammation and suppuration in the omental part of the peritoneum, which had been cut during the operation. The suppurating matter made its escape by an opening left at the upper part of the wound. At the end of six weeks the suppuration and inflammation had disappeared, and the woman was dismissed cured.

British Hospital Reports.

ST. GEORGE'S HOSPITAL.

Strictures.

THERE is a ward (Egremont) especially appropriated for the male patients who labour under these affections of the urethra. It contains seven beds, and of these seven three are under the care of Mr. Brodie. The first of these is very simple, and is yielding slowly but surely to the use of the bougie, introduced alternately by Mr. Brodie and the house surgeon. The second is an obstinate case, combined with great tenderness of the urethral passage posterior to the stricture and fistula

in perineum. This patient has also an abnormal elongation of the prepuce, caused by a vicious habit followed in early youth. The bougie is introduced about once every week only, as the patient complains of great pain afterwards, to relieve which he is frequently obliged to have a starch opiate injection. The third case is of a different and more obstinate nature than either of the preceding. The patient's name is Clark, and he has been under Mr. Brodie's care, either as an in or out-door patient, for upwards of a twelve-month. He is naturally of a full habit, and hale, and rubicund in appearance, but this high flushed state of health has very much decreased within the last three or four months. On his first admission he was treated with common bougies, gum elastic catheters, and sounds of the smallest size; but these were found of no avail, and a whalebone bougie, tapering downwards to a point, was then tried, and with but little better success. These means having been tried for some time, and without success, Mr. Brodie remarked that the best plan that could now be pursued would be to divide the stricture with a lancet, in the groove of a catheter, in the manner recommended by Mr. Stafford, and then to pass bougies afterwards, and in that manner to keep the stricture open, as far as was practicable. He (Mr. Brodie) considered that this plan (which was only to be adopted in cases of urgent necessity like the present) was a good one, as far it went, and was certainly preferable to cutting down upon a stricture through the perinæum. He purposed, therefore, bringing an instrument with him, which he had ordered to be made for the purpose, at his next visit, and he would then operate.

At the next visit, it was found that since the last attempt to pass an instrument, the patient had been seized with great pain in the perinæum, urethra, and loins, extending downwards along the course of the meatus to the bladder. To relieve these, he had been obliged to take opiates, and to be kept quiet at rest in bed. He had also, according to the house-surgeon's report, passed some pus with his urine. Mr. Brodie, however, doubted the fact of its being pus, from the circumstance of there being no blood mixed with it, which, as he remarked, is a very rare occurrence. We should also state, that from the irritated state of the mucous membrane of the urethra, behind the stricture, the same membrane of the bladder has become affected with chronic irritation, to relieve which the patient has repeatedly taken the pareira brava with great effect, a medicine which, as Mr. Brodie observes, has been most ignominiously and unjustly expelled from the Pharmacopœia of the College of Physicians. It has a very great influence in cases of irritable bladder, lessening very materially the copious secretion of ropy mucus, as well as diminishing the inflammation and irritability of the bladder. It is

given in the following manner:—Take half an ounce of the root of pareira brava, add to it three pints of water, and let it simmer gently near the fire until reduced to one pint. The patient is to take from eight to twelve ounces of this decoction daily. From the above circumstances the operation for dividing the stricture was postponed until a more fitting and favourable opportunity should present itself; it being a maxim with Mr. Brodie, that where there is any constitutional disturbance it is better not to meddle with the stricture until such disturbance shall have passed over. We shall continue our notes of this case.

Injury of the Hip Joint.

A boy, named Kennett, aged nine years, and of a light scrofulous complexion, was brought to the hospital from the country (Deal, we believe) having received, a twelvemonth before, some injury to the hip-joint. The history of the case, as far as we could learn from the confused statement the boy made, was, that he had fallen and struck the hip, immediately after which he felt pain at the anterior part of the groin of the same side, and three months afterwards the limb began apparently to shorten, so that he was obliged to raise the heel, and walk upon the toes of the affected side. On examination it was discovered that the hip-joint was ankylosed, and moved, not upon, but with, the pelvis; turning out the foot gave him great pain, and some slight crepitus could be indistinctly felt about the joint. The boy had been repeatedly blistered, and Mr. Brodie gave it as his opinion that the case was a most obscure one. There might be fracture near the neck, or separation of the epiphyses of the bone, or there might be merely thickening, and consequent stiffness of the joint, from the original injury. He recommended that the boy should be taken to Brighton, and undergo a regular course of shampooing. The boy was taken from the hospital by his friends a few days afterwards.

ST. BARTHOLOMEW'S HOSPITAL.

Moveable Tumour in the Thigh.

A young lad was admitted into the hospital with a tumour situated about midway between the inner condyle and neck of the femur. It was of an osseous hardness. The patient, in his history of the case, says it originally existed much lower down in the thigh, close to the inner condyle, and adds, that he received a violent blow exactly on the tumour, which knocked it up. He can move it up or down at pleasure. Mr. Earle thinks it to be an exostosis, which was attached to the femur by a very slender weak neck which was broken by the violence above mentioned. The patient is at present on low diet, and Mr. Earle will shortly (if, in the meantime, the tumour does not disappear) cut down on the part and remove it.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London;
Session 1832—1833.*

LECTURE LXXIX., DELIVERED APRIL 1, 1833.

GENTLEMEN,—From the observations which I made at our last meeting, you may infer, that there is great similarity between the *subcutaneous nævus* and the tumour called by Mr. John Bell the *aneurism by anastomosis*. You should remember, however, that the latter is characterised by blueness of the skin, and a throbbing synchronous with the heart's pulsation. The swelling is emptied of its blood when pressure is applied, but, on the removal of such pressure, the blood quickly returns into the tumour. Whatever has a tendency to quicken the circulation renders the part more turgid, prominent, and discoloured. At birth, aneurism by anastomosis is often a mere speck or mark; but, on the arrival of puberty, it becomes large, and is apt to burst, in which event it bleeds so profusely as often to endanger the patient's life. In females, in whom aneurism by anastomosis is more common than in males, these discharges of blood more frequently present themselves at the menstrual period; and numerous instances have been met with, in which the bleeding returned every month, and became a substitute for menstruation. Aneurism by anastomosis is most frequently observed on the face, the scalp, the neck, or the upper part of the back, and sometimes on the hands and the feet. I have seen one example on the hand, but many about the face and head. The eye has also been the seat of the disease, as you may learn by referring to the *Med. Chir. Trans. of London*, in which such cases are reported by Mr. Travers and Mr. Dalrymple. This kind of tumour is described by Mr. John Bell as a congeries of small arteries, expanding into, or communicating with, con-

siderable cells, as a substance resembling the gills of a turkey cock, or the texture of the placenta, spleen, or womb. Baron Dupuytren observes, that their structure, and occasional turgescence, give them a resemblance to the erectile tissues, such as are exemplified in the glans penis, clitoris, nipples, &c. Many surgeons have considered this disease as consisting of a morbid cellular structure, through which the blood passes from the arteries into the veins. These cells, however, might perhaps with more propriety be considered as presenting the sections of large arteries. The best authorities do not entirely coincide respecting the pathology of the disease, though all agree on one point, namely, that the subcutaneous nævus, or aneurism by anastomosis, is a new formation, charged with blood, and that, when cut, it bleeds most profusely and dangerously. Whatever plan you choose to try in the treatment of it, I should say, you must at all events not expose the patient's life to danger from the occurrence of hæmorrhage. I know of nothing that would be more likely to endanger a practitioner's reputation than a deviation from the principle or rule which I am now inculcating. Supposing you make use of a cutting instrument, therefore, whatever you do, don't cut into the tumour, but cut it out; make your incisions at some little distance from it, and remove it whole; this is the maxim of Mr. John Bell, and, as the saying is, it deserves to be written in letters of gold. If you cut into the tumour, it will bleed profusely, and your patient may die in two or three minutes, especially if the subject of operation be a child, in which the sudden loss of a moderate quantity of blood would suffice for the production of the fatal event. Besides the above important objection, let me observe, that if you only cut into the tumour, and do not remove every particle of it, though the patient should not die of hæmorrhage, he would not receive any substantial and permanent benefit, because the part of the disease left behind would grow with surprising rapidity to even a larger size than what it previously had. Hence, the safest practice is to make the incision into the sound parts around the tumour, and not into it.

Even, with these precautions, gentlemen, the operation is not altogether free from danger. Many cases are recorded of a fatal termination from loss of blood after the operation. Mr. Wardrop, in a manner that reflects great credit on his candour, has recorded an accident of this kind that happened in his own practice; the subject of it was a child; the tumour was of the size and form of half an orange, and was situated on the back part of the neck. The bleeding was so profuse, that the child was lost before it could be suppressed. On examination of the part, it appeared that an artery, of the diameter of a common quill, had been divided. Such misfortunes have made surgeons shy of using the knife for the removal of nævi, and led them to turn their attention to other plans. One of these consists in passing a double ligature through the tumour, and tying one part of it over one side of the base of the swelling, and the other over the opposite side of it. The only danger that can here arise, is from the irritation and sloughing induced by the ligature. If the constitutional and local disturbance be kept within certain bounds, and the sloughs separate favourably, the patient will recover. When the risk of hæmorrhage prohibits the removal of the tumour by the knife, no practice is perhaps more eligible than the ligature. Another mode of treatment, long ago proposed and often tried, is that of tying the principal artery leading to the nævus. Amongst others Mr. Hodgson and Baron Dupuytren have tried this practice, and the results were not satisfactory. In the majority of cases, the disease recurs after a certain time, and grows again as rapidly as ever. Yet, it must not be concealed, that this method has sometimes cured the disease, and we know that tying the carotid, as was done by Messrs. Travers and Dalrymple, accomplished the cure of two examples of this disease, formed in the orbit, and occasioning a protrusion of the eye. Another plan is that of destroying the tumour with caustic; this practice has sometimes been followed by Mr. Wardrop. Then, gentlemen, I have to mention to you the variety of treatment, which has sometimes been adopted, founded on the principle of exciting a degree of inflammation in the part, but not so violent a degree of it as to produce sloughing. With this view different stimulant applications have been employed. A stimulating fluid has sometimes been injected, by means of a very fine syringe, into the texture of the tumour. This plan has sometimes answered; but, I believe, only for very superficial nævi of small size. Nævi have been known to undergo a spontaneous cure, when accidentally attacked with inflammation excited by fevers, and hence it has been proposed to endeavour to excite the requisite degree of inflammation in the swelling, by the insertion of vaccine lymph. I have not tried this remedy myself, but have sometimes succeeded by applying the nitric acid and nitrate of silver. The late Mr. Abernethy

was an advocate for treating nævi with pressure made with a bandage; if it answer, it must be on the principle of its producing the requisite inflammation in the tumour, for the production of a total change in its texture. In the Med. Chir. Trans. you will find a paper by Mr. Macilwain in favour of the seton as a means of curing nævi.

Gentlemen, having finished this subject, I may now consider *tumours of the encysted kind*. *Encysted tumours*, commonly called *wens*, are composed of cysts, of which the texture varies in different cases; but generally they are of a globular form, and when free from inflammation, are unattended with pain. They have been divided into three kinds; the first from the contents bearing some resemblance to honey is called *Meliceris*; the second *Atheroma*, from its containing a pultaceous or pulpy substance; the third, being filled with a substance like suet, receives the name of *steatoma*. These terms are applied to the more common forms of encysted tumours, but there are many encysted tumours, which do not contain any substances precisely corresponding to those now specified. The atheromatous tumours, which are situated upon the occiput and the back of the trunk, have remarkably dense, strong, tough cysts, while other cysts, met with on the face, are exceedingly thin. The cysts, therefore, are found to vary in their density in different situations. They have generally only one cavity, but, in some cases, they are made up of separate cells, which may be of different sizes. In certain examples, you will find them adherent to the skin and to the surrounding and subjacent parts. In a few cases, they attain an immense size. In general, however, their size varies from that of a pea to that of an orange. Fatty or steatomatous tumours are sometimes as large as a cocoa nut. Cysts, containing hydatids, and connected with the ovary, frequently acquire an enormous size. Here is a cyst, which I removed from the body of a man, who died two years ago in the King's Bench. Feeling a fluctuation I made an opening into it with a trocar, but hydatids prevented the issue of the fluid, and I feared, at first, that my operation was what Sir Astley Cooper terms *dry tapping*. This cyst was connected to the liver, and contained seven gallons of fluid, and hydatids of all sizes. Here is a specimen of an ovarian cyst of prodigious magnitude. These cysts are frequently divided by septa into distinct cavities. I opened a woman a week ago, a patient of the Bloomsbury Dispensary, who had a collection of cysts adherent to the mesentery. As much fluid was discharged as filled a pint and a half; it had the consistence and appearance of turtle soup, though not precisely the taste (*a laugh*). I had tapped her several times before she died, and let out various quantities of the same fluid. Steatomatous encysted tumours sometimes contain, in addition to their characteristic suetty contents, calcareous matter, and even teeth or

hair. The hairs found in encysted swellings have neither tubes nor bulbs. Tumours of the encysted kind are very frequently situated under the skin, where Sir A. Cooper conceived them to be formed by obstruction and enlargement of the sebaceous glands. This preparation, which Sir A. Cooper was so obliging as to make me a present of, illustrates the fact: here you see the cyst, with a duct leading from it to the surface of the skin, in which duct a black bristle is introduced. In the living subject the external orifice is denoted by a black point, which may be seen. Sir Astley Cooper finds, that these cutaneous encysted tumours, when they contain fluid, may be prevented from giving the subjects of them any serious annoyance by occasionally cleaning the orifice of the duct, and pressing out the contents. When those cysts occur near the eyebrow, they are generally situated under the orbicularis palpebrarum. In some persons there is an extraordinary tendency to the production of encysted swellings. A man, at an inn at Dartford, had an immense one on his head, which prevented him from wearing his hat, which was lifted up in a most ludicrous manner. You will find the particulars of this case in Sir Astley Cooper's Essay. This bust, which was taken after death, shows us the form and magnitude of an encysted tumour that was situated upon the back of the head. The surgeon, in this case, no doubt considered that the attempt to remove the tumour would not have prolonged the patient's life, though, in an earlier stage, it ought to have been taken away. The tumour, which I next show you, I removed from the epigastric region last year; it was connected with the cartilages of the ribs; and had proceeded to ulceration. I objected at first to remove it, on account of its size, and of its being already in an inflamed and sloughy state; but the smell was so offensive and oppressive to his family, and all who came near him, that I judged it advisable to perform the operation, large as the tumour was. The man did very well. Tumours of this description have sometimes been known to ossify. On the table we have a tumour, the cyst of which is completely ossified; it was taken from the liver. Here is another bony cyst, which was taken from the brain of a sheep.

The next preparation is a remarkably dense cyst, which was found between the cranium and dura mater of a young person; but the particulars of the case I am not in possession of. Some of the French pathologists distinguish encysted tumours, rather according to the nature of their cyst than their contents. The serous cysts are curable without excision; the fibro-cartilaginous are not so: the former may be cured like a common hydrocele. This is the doctrine of some modern French surgeons, though I do not admire the practice to which it leads. Some cysts throw out a horny substance: I removed one of this kind from the nates of a medical gentleman in this neigh-

bourhood (*a laugh*), which troubled him very much. Whoever is curious about these horny growths, may go to the British Museum, where he will see one resembling a ram's horn in shape: it was taken from a woman's head. Another curious growth of a similar form was given to Sir A. Cooper by Dr. Roots: it grew on a gardener's head at Kingston, and, I believe, was successfully removed. Many years ago, I saw a horn cut away from the scrotum by the late Sir James Earle. It is in the museum at St. Bartholomew's, I believe, at the present time. I will now mention to you the treatment of encysted tumours:—those which are subcutaneous, and considered by Sir Astley as consisting of an enlargement of the sebaceous glands, in consequence of an obstruction of their duct, you may keep from enlarging, or becoming troublesome, by introducing a probe occasionally into them, pressing out their contents and afterwards maintaining the aperture clear; thus you will do away with the necessity of extirpating them. The generality of tumours, however, cannot be so easily managed. In some few cases, if inflammation attack the tumour, and lead to effusion of coagulable lymph in the cyst, so great a change may take place in the organisation of the cyst, that it may cease to renew its usual secretion, and the disease be finally cured. The plan of puncturing the tumour, letting out its contents, and then applying caustic or stimulating lotions is not a safe one. It not only generally fails in curing the disease, but is attended by some hazard. It has been known to give rise to the production of a fungous growth, accompanied by considerable pain, irritation, and the most dangerous disturbance of the system. The proper practice consists in dividing the skin freely, and detaching the whole cyst without wounding it. Sir A. Cooper first makes a section of the cyst, cuts it in half, as it were, and then dissects out each half separately. If the cyst, or any portion of it, be not removed, the patient will be likely to be afterwards harassed by the formation of a fistula, and even by the occurrence of fungous growths.

Another kind of tumour, which here I shall only advert to cursorily, constitutes a variety which can grow only from a mucous membrane, and is well known by the name of *polypus*. I only mention *polypi* in the present place for the sake of arrangement, and because I am considering the subject of tumours in general; but, in a future lecture, I shall notice polypi of the nose more particularly. Polypi are of three kinds, the *soft* or *gelatinous*, the *fleshy* or *sarcomatous*, and the *malignant* or *medullary*, which, in fact, partakes of the character of fungus hæmatodes, and is therefore improperly regarded as a polypus at all. The common polypus is soft, and of a light grey colour, not very vascular, and therefore not disposed to bleed much. It is not characterised by any tendency to become malignant.

Whatever inconvenience and pain may be experienced by the patient arise from its pressure on the contiguous parts, and its obstruction of certain canals or passages. It is mostly of a pyriform shape, and has a slender neck or pedicle. The neck generally remains almost of the same diameter and thickness as at first, but the body expands and acquires a broader shape, which, however, is frequently accommodated to the form of the cavity in which the tumour grows. Some polypi partake of a fibrous structure, and these are chiefly met with in the uterus. Some are so soft as easily to be twisted off with a pair of forceps: and this mode of removing, then, is called *extraction*. Polypi of the uterus are commonly removed with a ligature, applied with the aid of a double canula, like what I now show you; yet a few practitioners prefer cutting through the pedicle.

Another kind of tumours, which I shall here notice, are *warts*, which seem to be excrescences from the cutis, or tumours formed upon it. At first they are always covered by cuticle; but after they have risen above the surface of the skin, their apex assumes an expanded or cauliflower form, while the thin base remains either of its original thickness, or does not, at all events, increase in diameter so fast as the upper part of the excrescence. The deep part of warts in general is very sensible, highly vascular, and disposed to bleed freely when cut. These adventitious growths cannot long resist the application of stimulants; under such treatment they speedily diminish, dwindle away, or fall off. The stimulants for this purpose in common use, and, I may say, the best, are the nitrate of silver, the muriated tincture of iron, the sulphate of copper, a mixture of savine powder and subacetate of copper in equal proportions, and the concentrated acetic acid. There is one species of warts which may be said to approach polypi in the nature of their texture: they are seen about the rectum of both sexes, and on the perinæum and parts of generation in females. They may generally be cured by stimulating applications; but if these should fail, the best plan is to remove them with the knife.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XI.

Dysentery—Tympantitis.

GENTLEMEN,—I drew your attention briefly, at my last lecture, to the subject of dysentery; I stated that its anatomical character is now known to be inflammation of the great intes-

tine, and gave it as my opinion, that, in many cases of the epidemic, disease of the large intestine occurs under one of two conditions, either as secondary to typhus fever, or with an extension of the inflammatory process into the small intestine. These circumstances should, I think, be always taken into consideration in cases of epidemic dysentery; but the ordinary sporadic dysentery of this country, which we have now to consider, is, generally speaking, an inflammation of the large intestine. The old doctrine on this subject was, that dysentery was the result of an irritation caused by the presence of scybalæ in the colon; and the indication was to attempt their removal by purgatives. You will find this opinion put forward in many of the older authors, and that the plan of treatment which they recommend is in perfect accordance with their notions of the disease. It is a very curious fact, however, that in this country these hard faecal masses, or scybalæ, are very seldom met with in cases of dysentery. During the epidemic of dysentery, which occurred in Ireland in 1818, a series of clinical investigations, was made on an extensive scale by Dr. Cheyne, who at that period had charge of the Hardwicke Hospital; and he states, that, on a strict examination of the discharges in a vast number of cases, no scybalæ could be discovered; and in the sporadic cases, which we receive from time to time into the Meath Hospital, I have never found that the patients passed them. It is a great error to think that dysentery depends on the presence of scybalæ; the notion is now shown to be founded on a false pathology, and the treatment which it inculcates decidedly bad. You will be convinced of the latter when you recollect that the disease is inflammation of the great intestine, that its effect is to throw the muscular fibres of the gut into violent and painful contractions, and that the existing mischief must be therefore greatly increased by the exhibition of strong purgatives. For a knowledge of the true and scientific treatment of this disease, we are indebted to the light which modern pathology has shed upon practical medicine. We now employ purgatives with extreme caution, we use general or local bleeding, according to the urgency of the case; and we treat the disease as an inflammatory affection of the lower intestine demanding active depletion. All writers are unanimous in recommending the employment of the lancet, in cases of acute inflammation; and acute dysentery is one of those cases, in which general bleeding seems to have the best effect. Dr. Cheyne states, that in this disease the most decided relief resulted from the use of the lancet. He says that in several cases in which there were excessive pain and tormina, and in which nothing was passed for several days but mucus and blood, as soon as venesection had been performed, the patients became comparatively easy, and passed large quan-

tities of feculent matter. He also found that the blood drawn was buffed and cupped; and states that his experience led him to conclude, that this disease was best treated by the lancet. Dr. Mackintosh, who has had great experience in dysentery, says, that laxatives will act with the best effects, when blood-letting has been premised. In fact the utility of general bleeding in dysentery is established beyond any possibility of doubt; and those who object to the use of the lancet object to it on theoretical, and not on practical, grounds. As a proof of this, you will see a great many cases, in which decided relief is obtained by a natural hæmorrhage from the bowels; and this I think ought to be sufficient to overcome the doubts of those who are sceptical as to the value of general bleeding in acute dysentery.

Next to bleeding, the best thing you can have recourse to is the free application of leeches, a practice not sufficiently appreciated or followed in this country. I would advise you to apply leeches freely, along the course of the colon; and if the tenesmus be constant and distressing, round the anus also. The case, in which the application of leeches round the anus is attended with the greatest relief, is that in which the tormina and tenesmus are excessive, and in which a quantity of blood is found blended with each discharge. After you have applied the leeches, I would strongly recommend you to direct your patient to sit in a hip bath for some time, and you will find that he will experience great relief, because the bath will act as a fomentation, and promote the flow of blood from the leech-bites. I have often seen the application of a dozen leeches round the anus, followed by the hip bath, attended with the most rapid and signal advantage in dysentery.

Many persons are in the habit of giving small doses of some mild saline laxative in this affection; of this practice I cannot speak much from experience, and I think more benefit will be derived from the free use of demulcents, gum-water, whey, barley-water, and linseed tea. But the internal remedies, on which we chiefly rely in the treatment of dysentery, are mercury and opium. Blue pill and Dover's powder are an excellent combination, so are calomel and opium, and you may give either of these remedies alternately with a mild laxative, whenever you are led to suspect an accumulation of fecal matter in the bowels. In very bad cases, it will be necessary to continue the mercury until the mouth is affected; but in the sporadic dysentery of this country you will very seldom be under the necessity of bringing on actual salivation.

Permit me here, gentlemen, to make a few observations on mercurial action. In treating a case of dysentery, it does not, in the first place, follow as a matter of course, that you will cure your patient by subjecting him to the full influence of mercury. You are not

to expect that salivation will be always attended with success. There is another point which should never be forgotten, although it is one which I believe has not been sufficiently considered. It is a common idea with respect to the administration of mercury in cases of local inflammation, that if you produce salivation, you do a great deal towards accomplishing a cure, and this is true in most cases. Many persons are of opinion, that it is the ptyalism which carries off the disease, and hence it is that we so often see the principal share of a practitioner's attention directed to produce salivation *at all hazards*. This is the history of the medical treatment ordinarily pursued in warm climates, where such vast quantities of calomel are given. Here the idea seems to be, that the disease is to be subdued by salivation alone, and accordingly the practitioner "throws in" mercury, an expression evidently arising from the enormous quantities given. There are many cases on record, in which eight hundred and even one thousand grains have been given for the cure of a single local inflammation. But it is remarkable, that, in several cases in which vast doses have been given, no ptyalism has been produced, and thus it frequently happens, that the practitioner goes on increasing the quantity, lest he should have failed in consequence of not having given enough. All this practice is wrong, and founded on false notions; and I think that when you come to practise yourselves, you will be inclined to adopt the opinion, that, in cases in which mercury has been employed in the treatment of local inflammation, salivation is to be looked upon more as the result of the relief of inflammation to a certain degree than as its primary cause. For instance, suppose you are called to treat a case of acute enteritis or hepatitis; you give ten grains of calomel two or three times a-day, and find that day after day passes without any appearance of salivation. Another practitioner is called in, who bleeds the patient, and this is almost immediately followed by the appearance of salivation and relief. My friend, Staff-Surgeon Marshall, who is intimately conversant with the diseases of India, has informed me, that *he has never known a case in which abscess actually formed in the substance of the liver*, in which salivation could be produced; and that when the patient became salivated, he believed it to be a proof that there was no inflammation of an intense character, or that no abscess had formed. The greater the intensity of the disease, the less was the chance of salivation occurring, so that the salivation in certain cases appears to be the result of the same influence which produces a relief of inflammation, and not the cause of that relief. When, therefore, you have given mercury in free and repeated doses for twenty-four or forty-eight hours, and find no sign of salivation appearing, you should be cautious how you proceed, because in such

cases the inflammation may be of that intense character, which will not permit the mouth to be affected. Under such circumstances, the use of mercury, if rashly persevered in, will only aggravate the disease. In many cases of intense pneumonia, you will find that the patient will not be salivated until an advanced period, when, in consequence of the subsidence of intense irritation, the mercury is, as it were, allowed to produce its effect on the salivary glands. You may also frequently observe instances of intervals between the salivation, in which, during the course of an inflammation, the patient's mouth becomes affected by mercury; but if he gets fresh symptoms of the original affection, the salivation disappears, and returns only when the new attack has been overcome by appropriate treatment. I think that, under these circumstances, we are authorised in considering salivation as the effect of a certain degree of reduction of inflammation, and not as its cause. You will see the importance of these observations, when you reflect, in how many cases of local inflammation practitioners are in the habit of trusting to calomel alone; not being aware of the fact, that inflammation of an intense character has a powerful tendency to prevent it from acting on the salivary glands. Be assured of this, that if, in any acute visceral inflammation, after you have performed the usual depletions, you find an unusual resistance to the action of mercury, you may, on that account, form a more unfavourable prognosis.

There is one point in the treatment of dysentery which it is necessary you should be acquainted with. Sometimes the symptoms steal on gradually, and the patient appears to be in a condition not at all dangerous, when, all at once, the disease explodes with violence, and exhibits an extraordinary intensity; the fever is ardent, the tormina excruciating, the tenesmus constant and harassing, the defecations frequent and blended with lymph and blood. Such an array of threatening symptoms must be met with a corresponding activity. In such a case as this I would bleed, leech, use the hip bath, and give free doses of calomel and opium; and if you were to ask me, to which of the internal remedies used I should attribute the most decided alleviating influence, I should say to the opium. Dr. Cheyne says, "after the lancet, the best remedy I know of is opium." He says further: if another epidemic, similar to that which he witnessed, occurred, he would have no hesitation in giving opium, in four grain doses, in such cases.

There was a very curious circumstance connected with the history of the epidemic dysentery of 1818-19. At one time the deaths happened to be extremely numerous, and every thing which the experience or ingenuity of Dr. Cheyne could suggest failed in arresting the disease, in many cases. An English physician, who happened to be in Dublin at that

period, and was in the habit of visiting the hospital, proposed the administration of large doses of cream of tartar, stating that he had tried it on several occasions under similar circumstances, and was convinced of its value. As the cases were not succeeding which had been treated after any of the ordinary modes, Dr. Cheyne consented to the exhibition of the cream of tartar, and allowed the physician to prescribe and administer it himself. Accordingly he proceeded to give it in doses of half an ounce every fourth hour. Its first effect, generally, was to produce violent distress, and to aggravate all the symptoms, but, after three or four doses, bilious and feculent stools came away, and the patient experienced the most extraordinary relief. Many cases, which had been considered desperate, improved and recovered, and Dr. Cheyne expresses his conviction, that many persons were saved by this practice, who would have been lost under the ordinary modes of treatment. One of the older German authors has also alluded to this singular efficacy of cream of tartar in the treatment of dysentery; and from the result of Dr. Cheyne's experiments, there can be no doubt that it is entitled to a high rank among the remedies usually employed. In case you should prescribe castor oil as a laxative, it will be necessary to combine it with mucilage of gum arabic and a few drops of laudanum; given alone, it will be likely to prove too irritating, particularly during the acute stage. In the advanced stage much benefit will be derived from a combination of castor oil with tincture of opium and a small quantity of oil of turpentine. This is not at variance with the pathology of the disease, for there is a period in this as well as in every other form of inflammation, when stimulants may be used with benefit.

Such is the treatment of the ordinary forms of acute dysentery; but it may happen that you will be called to a case in which you cannot employ these decided measures; and here I shall mention, that in all local inflammations it is of the utmost importance that you should act with judgment and decision in the commencement. Every hour is precious; a single day is worth much; and if two or three days are allowed to pass, and the treatment is inactive or indecisive, the patient too often sinks into the chronic stage or dies. Whenever you happen to be called to treat a case of acute local inflammation, attempt to cut it short as soon as possible; it is much easier to cure an inflammatory attack in its commencement, than to save the patient from the effects of it in the advanced stage. Now, if you should be called to a case of dysentery of some standing, and on your arrival find the patient lying on his back, his skin of a pale dirty hue, his eyes sunk and without lustre, his extremities cool, and bedewed with a clammy sweat; his pulse small, rapid, and feeble; his thirst ardent; his pains and tormina inces-

sent; and constantly passing from his bowels a quantity of fluid matter, blended with depraved mucus, lymph, and blood, with great irritation about the anus, and if these symptoms have lasted for some days you may be sure there is extensive ulceration of the lining membrane of the large intestine. How are you to act under such circumstances? The patient will not bear bleeding, or perhaps the application of a small number of leeches. Here your sole object must be to support your patient's strength; you must give wine (if the skin be cool), strong chicken broth, beef tea, jellies, &c.; you must wrap your patient in flannel, and have recourse immediately to anodyne and astringent injections, and you should blister the abdomen, taking care to remove the blister at a proper time, and not leave it on so long as may add to the existing irritation. You may also prescribe the acetate of lead, or the sulphate of zinc with tincture of opium. I have seen several cases of this kind in the Meath Hospital, in which the administration of the sulphate of zinc was attended with good effects. The best mode of using it is to dissolve ten or twelve grains of the sulphate of zinc in six or eight ounces of cinnamon water, with a proportion of laudanum, and direct this quantity to be taken during the twenty-four hours. Dr. Elliotson recommends the sulphate of copper, and you can employ it in combination with opium. In this way, by supporting your patient's strength, keeping him warm, paying attention to the state of his bowels, using counter-irritation, and prescribing astringents combined with opiates, (taking care not to check the discharge too suddenly,) you will often succeed, even in very bad cases. Before I quit this subject I may observe, that Dr. O'Beirne has succeeded in some cases, and in others has given great relief by the use of tobacco injections. You can understand this when you reflect, that tobacco acts powerfully on the general system, and produces effects somewhat analogous to bleeding. Like general bleeding it brings on faintness, vomiting, cold skin, perspirations, and feeble pulse. It is also a powerful anti-spasmodic, and Dr. O'Beirne states, that its employment has been attended with the best effects in several very bad cases. I have not tried this remedy myself, but I think it well worthy of a trial in the acute stage of dysentery, when there is room for an antiphlogistic treatment. In the advanced stages, of course, it is inadmissible.

We come now to consider the affection of the digestive tube, which merits a separate consideration, and this is tympanitis, or, as it is sometimes termed, meteorism. I shall not enter upon the general pathology of aëriform effusions into the abdomen; we are not acquainted with that peculiar condition of parts which produces them, but it is now established that we may have effusions of air, not only into the digestive tube, but also into every part of the body. The term tympanitis is

limited to effusion of air into the digestive tube, in all parts of which we may find it. We detect it in the stomach under two circumstances; first, as a recent and transient affection, as when it comes on after swallowing indigestible matter; secondly, in a more permanent form, as when it depends upon hysteria, hypochondriasis, or chronic gastritis. It may be also frequently seen in very young children, when there is feverishness with irritation of the digestive system. I recollect a very remarkable case of this kind, in which the distension was so great, and the pressure on the diaphragm so considerable, as to cause displacement of the heart upwards;—this, I believe, has not been mentioned among the causes of displacement of the heart. The symptoms of this affection are sufficiently obvious;—a sense of uneasiness and distension at the region of the stomach; when the effusion is in excess, a distinct tumour can be felt, and the sound on percussion, over the stomach, is like that of a drum. It often happens, also, that when the patient is shaken, a distinct sound of fluctuation is heard, a circumstance which more than once has led to the suspicion of the existence of pneumothorax, or empyema. There are also cases on record, in which the distension was so great as to cause rupture of the stomach, and effusion of its contents into the cavity of the peritoneum, causing intense inflammation and rapid death.

The effusion of air into the intestinal tube is extremely common in cases of acute enteric inflammation and gastro-enteritis, after the disease has lasted for a few days, and, as this is a matter of considerable interest, I wish to make a few remarks upon it. It is of importance that you should bear in mind, that this is one of the results of enteric inflammation, because many persons are in the habit of looking upon it, not as a mere symptom of another affection, but as a peculiar form of disease, forgetting that it may occur with, as well as without, inflammation. In consequence of this limited and imperfect view of the subject, they are in the habit of prescribing turpentine as a specific remedy for tympanitis. Now, I can say, that I have seen the most dreadful effects from the administration of turpentine in the tympanitis of acute enteric inflammation. The immediate effect is to produce a rapid diminution of the tympanitic swelling; but this is purchased at too dear a rate; for you will find next day, that there will be a violent exacerbation of the existing symptoms, and the tympanitis becomes worse than before. You should never, therefore, interfere in this way with the tympanitis of acute enteric inflammation, nor should you alter your practice on this account in the slightest degree, except where the tympanitis is so great as to interfere with the due performance of the function of respiration; but, in the advanced stage, after the twelfth or sixteenth day, when the fever has abated and the tongue is moist, I have frequently seen great advantage result from

the use of turpentine. *But as long as the condition of your patient admits of antiphlogistic treatment, be assured that the administration of turpentine is hazardous.* When the patient is in a low state, when you can no longer have recourse to bleeding or leeching, when the tympanitis is connected with an asthenic condition of the intestinal mucous membrane, then, and not till then, should you venture on the employment of turpentine. I shall return to this subject when we come to speak of hysteria.

I may mention here, that the occurrence of flatus in the intestines sometimes gives rise to dreadful suffering in that affection which has been termed windy colic. A person in the enjoyment of good health happens to take at his dinner or supper a quantity of indigestible food, he goes to bed without feeling any particular inconvenience, but about the middle of the night he awakes with an attack of pain and tormina, which extend from the hypochondria to the umbilicus. This subsides for a short time, and then returns with violence, and the patient often finds that it is relieved by pressure. In a short time the pains get worse, and the abdomen begins to swell, sometimes at one point, sometimes at another, as if the air was confined and pent up in particular situations. The patient begins to suffer indescribable anguish, he has great anxiety, extreme prostration of strength, his face is pale, his extremities cold, a cold sweat breaks out all over the body, and he sits bent forwards, with his hands pressed on his stomach to relieve the paroxysms of pain which come on with increasing rapidity. In some cases there is distressing hiccup, in some a large quantity of aqueous urine is passed, in some there are loud borborygmi, and the intestines may become so enormously distended, as to fall rapidly into a state of gangrene. Hippocrates has given a description of one of the forms of this disease, which terminates by the passage of air upwards and downwards, by which the patient obtains relief; this he calls dry cholera. This windy colic is an exceedingly violent disease: one of the first cases of it, which I witnessed, presented such an array of alarming symptoms, that I thought every moment the patient would expire. It is, however, a disease which is generally easily managed if taken in time. One of the first things to be done is to apply heat to the abdomen by anodyne stupe, or warm flannel. Flannels wrung out of a decoction of poppy-heads, as hot as can be borne, will do a great deal of service, and in some cases will give complete relief, when assisted by the use of carminative draughts. But of all the remedies which I have seen, the most efficacious is an injection with tincture of assafoetida, turpentine, and opium. This is generally followed by speedy relief, the pulse becomes more natural, the belly soft, and the excruciating agony is relieved. This is the mode of treatment in which I have the greatest

confidence. After the acute symptoms are removed, it will be proper to exhibit a laxative, for the purpose of removing the exciting cause of the disease,—indigestible matter; unless you get rid of this, your patient is liable to a return of the attack, and even to an inflammation of the tube itself. Be not, therefore, satisfied with merely relieving your patient; watch him carefully, and, by a proper treatment, obviate a recurrence of the symptoms, and prevent any tendency to inflammation.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS AND CHILDREN,

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE XV.

Literary Education of Children.

GENTLEMEN,—A question of deep importance to the infantile growth and health presents itself to our notice, with regard to the proper time of commencing the literary education of children, or of sending them to school. The ablest philosophers and physicians have written on this question, and therefore I shall offer a few remarks upon it.

I pointed out, in a former lecture, the imperious necessity of exercise in the open air, for insuring the development and health of children. I stated, that the more a child plays in the open air, when the weather permits, the better. I agree with those who condemn the practice of sending children of three or four years of age, "out of harm's way," to school; first, because confinement is most prejudicial to their development and health; and secondly, because a child of seven years old has not the faculties of mind sufficiently developed. Every one of us is aware, that we have learned more at twelve or fourteen years of age, in one month, than during the whole period of our previous scholastic pursuits; and that persons at the adult age will acquire more information in one year, than during all the former time they had spent at school.

But I cannot agree with those who maintain, that a boy or lad should not be sent to school sooner than his twelfth or fourteenth, any more than with those who will recommend removal at the sixteenth, year, as is now almost the general custom.

Common observation proves, that activity of body and mind is characteristic of childhood. Nature has implanted this in the human constitution. The exertions of a child are almost incessant; it cannot remain quiet; it is in constant motion, which invigorates its body by accelerating the circulation of the blood for the nutrition of every organ. It is therefore unnatural to confine a child of three years old, two or three hours in one posture, as is

usual in schools, thereby depriving it of that exercise, which is so conducive to its development and health. No child under six, and, according to some, under ten years of age, should be confined and drilled at school. Precocious mental exertion often does irreparable mischief, though parents in general evince great solicitude, to exhibit their offspring as prodigies of learning. The sight of books is disgusting to most young children, because their understanding, at an early age, is incapable of comprehending the rudiments of their own language. Premature study is an irksome and highly injurious labour, and is never relished. A boy will learn more in a few months at the age of twelve or fifteen years, than during the whole period of his previous life. It is easy to account for this fact, when we consider that a boy who is not sent to school, but allowed to take exercise, has his mind and body well developed; whereas a child immured in school, from nine in the morning until three in the afternoon, has his growth arrested, and his health injured, is more likely to become a cripple, or to be cut off by the diseases of early childhood. He is, in truth, debilitated both in mind and body. Nevertheless, the young mind should not be neglected; but it may be enlarged and instructed by being engaged in the study of natural history, or the various productions of the world around it. An hour's instruction at home ought not to be exceeded during the first three or four years; and due allowance must be made, for the difference of infantile intelligence. Some children have no taste for learning, and will never become distinguished under the ablest masters. It is therefore cruel and barbarous to inflict corporal punishment, in this, or indeed in any case, on children. The barbarity of a brutal pedagogue has often laid the foundation of tedious or incurable disease, and, in some cases, has caused death.

Humanity compels me to notice the baneful system of discipline, generally practised in our boarding and public schools.

In most schools, children of all ages, from five years old, are obliged to rise at six o'clock in the morning; there is no distinction made between the young and the old, the delicate and the robust. The period of study is about an hour or two, and then there is a short morning walk. After breakfast, which is about nine o'clock, the toil of the day commences, and continues until two or three in the afternoon. During this time, girls are subjected to the most unnatural and injurious discipline; they are compelled to sit in one position; and should they, in consequence of fatigue of certain over-exerted muscles, which is inevitable, swerve from the perpendicular, they are invariably subjected to some artificial contrivances to remedy this natural consequence. Back-boards, collars, stocks, stays, and weights, are put in requisition. When the girl bends forwards, which she must inevitably do after over-straining the muscles of the back, (and

her mistress should do the same thing were she to sit upright for ten minutes,) a back-board and weights are employed to remedy the evil. Should she lean to one side, a weight is attached to the opposite arm. When the muscles of the neck are fatigued, and the head falls forwards, a steel collar with two sharp prongs is placed on the neck and under the chin. While all this torture is being inflicted, the dancing-master beautifies the feet by placing them in stocks, or in iron shoes. Need I denounce this unnatural and injurious system? Every one endowed with common sense—every member of our profession, must condemn it. The result of this plan is inevitable deformity of the spine; and hence there are few girls who escape it. Boys are not subjected to this barbarous discipline; their symmetry happily claims no attention; they change their position as often as nature dictates whenever the muscles are fatigued; they run about, when allowed to take exercise, they strengthen their constitutions and escape deformities. When girls are allowed to take exercise, they are marched in regular order—in regular rank and file; their slow gait must be according to strict rule; they walk up and down some dusty road; they march with a solemn pace, as if at a funeral; for to run or jump would be contrary to all etiquette and polite usage, and would gain for each transgressing individual, the title of romp. When these unfortunate children return to their miserable abode, they are allowed abundance of bread and treacle before dinner, on the grounds of economy; the same description of food is finally placed before all at dinner; likes and dislikes are out of the question; no allowance is made for the difference of taste; and woe betide any unfortunate creature who murmurs discontent. After dinner there is a short walk allowed, then study, next tea, and finally bed.

The attitude of girls at study, needle-work, writing, drawing, the piano, and harp, has a tendency to distort the spine; and make crooked and weak backs. Brothers of the female victims, who have the same constitutions, escape, for the reasons already assigned. Girls are either placed on a stool that has no back, or on a chair which has a perpendicular slender one; the first relieves the back more than the second, but both are bad, because the individual ought to be allowed to change her position whenever it is irksome. Strong stiff stays are also injurious. Tight lacing prevents the growth of the chest, impedes the breathing and action of the heart, causes palpitation, and renders the compressed parts a load on the lower part of the spine, which bends to one side. Want of proper exercise and tight lacing, are the causes of spinal curvatures in girls; and hence we can scarcely see a young lady with a straight back. Active peasant girls, on the contrary, are models of symmetry and beauty; because they are not subjected to the causes just described.

M. Rousseau, who has written admirably

upon the education of children, maintains that they should never be questioned about things for which it may be their interest to deceive. It is contrary to one of the fundamental principles of our unequalled constitution, that any man should accuse himself; and the same rule, founded on reason and justice, should apply to children. It would be well if parents and preceptors bore it in recollection, when they call upon children to accuse themselves of some petty delinquency, as breaking glass, &c. In such cases the mischief is done, generally, by accident, or unintentionally; and we cannot repair it by chastisement or cruelty.

The attention of a child should not be fatigued by long study. It is better to acquire one idea, than load the memory with twenty at a time. Mr. Edgeworth taught a child to read any word in the English and Latin languages in the space of eight hours—not successive hours—but at the rate of six or seven minutes per day. He also taught a child, of four years of age, to pronounce any word in the English and French languages in the same space of time. He holds, that more information would be communicated by this method in large schools, in one-tenth of the time required by the usual plan of teaching. The plan of education suggested by his sister, Miss Edgeworth, is perhaps the best ever proposed; it is infinitely superior to that of Pestalozzi, which commences so soon as the infant is capable of perception, which inflicts a premature and excessive action of the dawning intellectual faculties, injures the nervous system, and consequently every function of the body and faculty of the mind, and therefore is injurious to the growth and health of children. Bodily exercise ought to follow that state of rest in which children are while learning their lessons.

Few children have a taste for study, especially at first; and many lose their health, because premature and excessive mental exertion causes enervation, deranges the whole functions of the body, induces feebleness, and arrests development. Infantile aversion to learning is also increased by the erroneous systems and severity of the majority of pedagogues. Many masters attempt to exact too much, and expect impossibilities from children, which inspires great disgust, and sometimes so much fear or terror, as to injure the best constitution. The truth of this statement was admitted by many celebrated writers. I shall mention one example only.

We find that Cæsar said of the Germans, they were robust in body, on account of the negligence with which they treated the mind; they were under no restraint, were not obliged to study, but allowed to follow the dictates of nature from an early age, to enjoy and to take exercise; and that this was the chief cause of their great stature, and that robust vigour, which excited the admiration of other nations. It is universally allowed by our profession that premature mental exertion is bad.

The intellectual faculties are differently

developed, according to the vigour of individual constitution; and hence some children will make a much greater progress in learning than others. It sometimes happens that children whose faculties are not the most precocious are generally most robust; but there are numerous exceptions to this position. I fully agree with those who consider severe and precocious study a great obstacle to the health of man.

I dwell upon this point, because the present age is distinguished for its ardent desire to diffuse knowledge; and this disposition impels most parents to render their children at a very early age prodigies in literature and even the sciences, at the expense of health and long life. Parents now adopt the adage,

Ante barbam, docet senes;

or to give a free translation, the child teaches his grandfather.

I feel convinced from some observation, that children should not be sent to school until they are five or six years old. Before this they can acquire a vast deal of knowledge and information, by learning the names, uses, and properties of the immense number of objects that surround them.

The first rudiments of learning should be taught by parents, while children are of a tender age; perhaps after the seventh year. There are many superior advantages in paternal education. The follies, vices, and bad conduct, acquired in schools by imitation, are all avoided and prevented.

It is urged, however, in favour of education in public schools and colleges, that it sharpens the wit and enlarges the mind more than parental instruction. The truth of this statement must in general be admitted; but still such institutions are open to serious objections, on account of the numerous vices which are learned by young children from their companions. The discipline in most public schools and Colleges, is highly objectionable and unnatural. There is no allowance made for difference of age or vigour; and in some of our public schools the stronger boys are allowed to tyrannise over the weak, and, in some instances; to inflict such corporal injury as to cause death. It is exceedingly unaccountable on what grounds the masters of schools sanction such abuses; but "the schoolmaster" who is now abroad, does not appear to have as yet visited them.

Though there are many parents too strict and severe towards their children, there are others who indulge them too much, by gratifying their importunities, and rendering them self-willed, peevish, and fantastic, to the great injury of their health. We have all observed examples of "a spoiled child," and have noticed its delicacy and debilitated constitution. Many bad methods are still employed in the correction of children. They are often frightened by being shut up in dark apartments, threatened with cannibals, giants, ghosts, &c.

and their tender imagination is so excited; that convulsions, and even death, have too often been induced. Nurses and servants are highly reprehensible for such detestable and dangerous conduct. I have known instances in which children awoke suddenly at night, screamed violently, and appeared extremely terrified, in consequence of dreaming of the frightful fables told them by their nurse. We even observe that the bad effects of such impressions continue to the age of puberty, and sometimes later; as many children are afraid to sleep in an apartment by themselves, or to enter it without a light; and there are some adults who have the same unfounded fears. Children should never be frightened, either to tranquillise them, or a mode of correction.

Another error in the management of children is committed by parents, when they caress and show more affection to one child than to another. This excites jealousy and envy, and is prejudicial to health. Parents, who have perused good works on moral education, should also study those on physical education, to ensure to their offspring a sound mind in a sound body. But, alas! how few parents, however enlightened they may be, have the slightest knowledge of the management and preservation of the health of their children. Besides the numerous errors described in the preceding lectures, many more deserve exposure, but I shall notice the greatest of them only. Some parents are for ever "drugging or doctoring" their children. No medicine should be administered to children, without competent medical advice, whenever this can be obtained; because all medicines are injurious to children, unless when ill; and great judgment is necessary in prescribing them. Mr. Locke has left us an excellent comment on this error—(*On Education*). The diseases of infants are discovered with difficulty, because the subjects of them are unable to describe their sufferings, though every mother and nurse undertake their management, and often cause irreparable mischief. There is no want of medical practitioners in this kingdom at present, as the profession is much too crowded, and therefore there is no difficulty in obtaining proper advice for the diseases of children; the poor even can procure it at hospitals and dispensaries. Having now concluded the hygiene and physical education of children, I shall next proceed to describe the nature and treatment of infantile diseases.

Infantile Medicine.—The term infantile medicine is applied to that branch of the healing art, which relates to the nature and treatment of the diseases of infants and children. The term infant is applied to man from the period of birth to the time he walks, when childhood commences; but some physiologists use the former term from birth to puberty; while others divide this period of life into infancy until the seventh year, and second infancy from that period to puberty. The

Latins comprehend both in the word *pueritia*; It was known to Hippocrates, that accurate and faithful observer of nature, that diseases were peculiar to different ages, and consequently that they differed in the first and second infancy. In the first infancy, both sexes are subject to the same diseases, as both have a conformity of organisation and functions, with the exception of the genital organs. It is about the end of the seventh year, that there is a marked difference between the moral and physical states of infants of both sexes, which is greatest at puberty. The father of medicine divided infantile diseases into two classes, which correspond to those changes or crises which mark the development of infants to the age of puberty, or the fourteenth or fifteenth year in this climate. The first he extended from birth to dentition, and the maladies of this class were chiefly those connected with the digestive and nutritive systems; and according to Etmuller (*Valtudinarium Infantile*) these arose from a particular alteration in the digestive system. The second embraced the process of dentition, and extended from the sixth or seventh month to a year and half, or two years. The irritation and pain in the gums during dentition, cause congestion of blood in the brain, which may be followed by hydrocephalus (water in the head), convulsions, derangement of the digestive system (stomach, bowels, liver, kidney, urine, &c.) causing emaciation, large head, abdomen, and joints, and exciting scrofula, or enlargement of the glands, both internally and externally, or that form of the disease called rachitism, or rickets. It is easy to explain the causes or reason why these diseases are excited by dentition. Every part of the body is connected by nerves, the irritation of a single branch of a nerve will derange the whole nerves of the body, and consequently every function in the animal economy, as all functions depend upon nervous influence or supply in the different parts. Thus toothach in the adult will cause loss of sleep and appetite, derangement of the bowels, of the senses, vision, olfaction, audition, gustation, and palpitation (touch), as well as of the intellectual faculties; or a slight wound on the finger, or any other part, will induce convulsions, or tetanus, or rigid spasm of every muscle in the body. It therefore follows, that a host of diseases may be excited by dentition or any local irritation, and this is universally admitted by the profession. Hippocrates stated in his *Apophisms*, sect. 3, that during dentition there were cutaneous eruptions, fevers, convulsions, diarrhoea—that infants were liable to many diseases during the first forty days, to others within the first seven months, and to some from seven months to puberty. He did not, however, give a general view of the etiology or causes of infantile diseases. The causes, assigned by all his successors, were vague and incorrect, until Stiel and Hoffman accurately explained the diseases of different ages, by the

predominance of certain organs, or, in other words, by temperaments. This is the source whence to deduce our prophylactic (preventive) and curative indications; and the hygienic and therapeutical means most proper to fulfil them. It also leads us back to generation, to the hereditary diseases of parents, and to the organisation of infants. There cannot be the least doubt, I apprehend, as to the resemblance of the features, and every part of the body, internal and external organs, between parents and children. It is this resemblance which proves the analogy of tastes, dispositions, vices, virtues, talents, and diseases between parents and their offspring. From this similarity of conformation between the organs of parents and infants, we must conclude, that the constitutions and disposition to diseases are transmitted from the former to the latter; and that the latter may be developed during infantile growth. Some deny the existence of hereditary diseases; but the records of medicine leave no doubt of the fact. Infants have been born jaundiced, affected with syphilis, and small pox, as I have repeatedly witnessed; and, in after life, have been affected with certain diseases of their parents, as of the liver, lungs, kidneys, &c. It is perfectly impossible, in the present state of science, to explain the causes of the malformations and diseases of the foetus in the womb; and a good-sized volume might be occupied with their description. I might occupy ten lectures with the account of these; but this would be of little use to you in practice. Suffice it to state, then, that repeated instances are recorded of the absence of all parts of the body, of the greater portion of the skull and brain, of some portion of the spinal marrow, of one or both eyes, ears, nostrils, arms, lower limbs, of the mouth, anus, urethra, vulva, imperforation of the digestive tube, malformation of each of the viscera in the head, chest, and abdomen. In fine, there is no form of infantile deformity, which you may observe, but has been already described.

Infants are born with hereditary, and connate, or congenital diseases, or such as they labour under at birth; and they are liable to many others common to adults, until they arrive at the age of puberty. I shall, therefore, confine myself to the pathology and treatment of connate or congenital diseases, and of all others which occur to the age of puberty. These will embrace most of those described in the works on the practice of medicine and surgery. The principles and practice of infantile medicine, however, differ materially from those adopted and employed at the adult age, and therefore demand attentive study and reflection. The peculiarities of the infantile and adult constitutions are widely different; and the diseases must be treated differently. In the treatment of diseases of infants, we must always remember their peculiar constitution; and that, at every age, some one or other of the organs of the eco-

nomy predominates over, and influences, all the rest.

The constitution of infants at birth, is characterised by a great proportion of white fluids, a mobility or weakness of the muscular; and an excess of susceptibility of the nervous and digestive, systems. The head is more voluminous in proportion than that of the adult, and the nerves are much more easily disordered. The trunk and the limbs are soft and delicate, the bones imperfectly ossified, the whole body almost a gelatinous mass—a bundle of nerves—a ganglion. The sensibility of the skin, of the mucous or lining membranes of the respiratory, digestive, and excretory organs, is also intense and easily excited. Some physiologists have contended that the cerebral and lymphatic systems predominate at birth; while others ascribe the predominance to the digestion. Hippocrates, Etmuller, Capuron, &c., entertain the latter; and most writers since the time of Sthal, including Bichat, the former opinion. It is difficult to arrive at a decided conclusion on this dispute, because we observe some infants, whose vivacity, rapidity of sensations, and cerebral affections unequivocally predominate over the digestive system, and others in whom the reverse occurs.

It is clear, however, that the vivacity of sensations, the avidity with which the infant exerts its organs of sense, and the remarkable influence of the digestive organs at this age on the brain, and the vast number of nervous disorders to which it is subject, prove the superabundant vitality of this organ. But all have observed the very excitable state of the digestive organs in infancy, by the continual want of aliment, the rapidity of digestion, and the disposition infants have to eat incessantly. The greatest care, therefore, is necessary in selecting aliment for infants, as the ingestion of improper articles of diet readily excites gastric and gastro-intestinal irritation, inflammation, and ulceration; colic, cholera, diarrhoea, lientery, &c., &c. The employment of improper food is one of the commonest exciting causes of infantile diseases. Most nurses give too much aliment, and of an improper kind, as I have already proved to you in describing lactation and the solid aliment proper for infants. The application of cold air to the skin and mucous membranes, is another fertile cause of diseases of infants. It is to be recollected, that the skin at birth is almost a kind of mucous membrane, which receives the impression of cold with pain, the transpiration, or insensible perspiration, is suppressed, and catarrh, coryza, or cold in the head, croup, and quinsey are induced. We also observe that portion of mucous membrane, which covers the anterior surface of the globe of the eye and eye-lids (conjunctiva), is irritated by the air, or by the discharges which sometimes may come in contact with it during parturition; and hence ophthalmia takes place in some cases of a purulent description, which,

unless properly managed, may cause loss of vision.

The mucous membrane of the bronchi, or air passages, is easily excited by cold air; and hence croup, whooping-cough, and inflammation of the lungs are readily induced.

Some infants have the lymphatic system predominant, as those who are pale, the glands enlarged, the abdomen tumid, the vivacity in general diminished. Children so affected have less energy of the brain, are taciturn, sad, and scrofulous or rachitic. In these, the glands of the neck, groins, chest, and abdomen, are irritated by cold, improper food, or internal inflammations. Nutrition is arrested on account of the enlargement of the mesenteric glands, which are often impervious to the chyle; emaciation follows, especially of the limbs and body; the head and abdomen enlarge; the bones are altered in structure; the child becomes rickety or scrofulous; and will often perish unless treated with the preparations of iodine, and nutritious aliment. When the abdomen and head are enlarged, and the rest of the body emaciated, the disease is called *tabes mesenterica*, and *consumption* by parents.

Adverting to the dangers to which an infant is exposed at birth, Professor Capuron gives the following graphic description:—"Man, said an ancient philosopher, appears to come into this world but to suffer. The father who begot him, the mother who conceived him, often transmit to him the germs of diseases, which continue to impregnate him during pregnancy. Arrived at the term of viability, the foetus cannot be born without suffering pain, and a crisis more or less tumultuous, which exposes him to great dangers, even to death, at the portal of life. When the infant begins to respire, behold the mark of new dangers! a crowd of external agents supervene, without ceasing, to chill and derange his frail organisation. Errors in diet during physical education, want of parental love, ignorance or prejudices of nurses, the storm of dentition, accidents which menace the period of weaning, epidemic and contagious diseases—such are the obstacles capable of arresting man at the commencement of his career."—*Traité des Maladies des Enfants*.

The helplessness, wants, and liability to diseases of new-born infants, are felicitously described by Lucretius (*De Naturâ Rerum*, lib. 5,) in these words:—

"Tum porro puer, (ut sævis projectus ab undis Navita,) nudus humi jacet, infans, indigus omni Vitali auxilio, quum primum in luminis oras Nixibus ex alvo matris natura profudit, Vagituque locum lugubri complet, ut æquum est

Cui tantum in vitâ restet transire malorum."

The diagnosis, or discrimination of the diseases of infants, is extremely difficult. I have already observed, that disease or disorder in any organ will derange the whole functions of the body, and cause such a variety of symp-

toms, that it requires great discrimination and a perfect knowledge of the principles of medicine, to enable us to form an accurate opinion. I have often been consulted in cases which were supposed to be diseases in the intestinal canal, when the mischief was in the head, and *vice versâ*. Infants have not the power of speech to communicate their sufferings, or if they are able to reply to our questions, little or no reliance can be placed upon their statements. In order to dissipate, as much as possible, the difficulties of diagnosis, we should, as in all cases of disease, listen with attention to the history given us, and then explore or examine all parts of the body, the brain and spinal marrow (cerebro-spinal system) the circulatory system (pulse), the respiratory, the digestive, the secretory, or alvine and urinary, and the muscular or locomotive system. We should first observe the attitude and movements, the expression of the countenance, the state of the eyes; and ascertain if there be any foreign matters between the lids, in the auditory canal (ear), in the nasal fossæ (nostrils); examine attentively the temperature of the scalp, the carotid and temporal arteries, the gums, tongue, mouth, throat,—abdomen by pressure on all its surface, which will enable us to detect enteritis (inflammation of the bowels), hernia, or rupture, and also learn whether there be prolapsus recti (falling down of the bowel), whether the testicles have descended into the scrotum, and we should finally inspect the limbs, joints and surface of the body, apply gentle percussion on the chest, and employ the stethoscope. The cries of the infant will also assist us in our diagnosis, and it is easy to distinguish those of pain from those of passion.

When the brain is affected the scalp will be hot, the carotid, temporal, and vertebral arteries will be pulsating violently, the infant will be constantly moving its head on the pillow, raising its hand towards the seat of disease, attempting to pull off the night-cap; there may be drowsiness, or excessive restlessness, the face will be flushed, the countenance anxious, the brow knitted, the eye-lids half closed, the eyes turned upwards, the pupils dilated or contracted, or, in popular language, the black of the eye will be enlarged or diminished, the head may be large, the fontanelles or openings unossified and pulsating, and there will be an abundant growth of hair. The infant will scream in its sleep, grind its teeth, and may be affected with strabismus, or squinting, or with total loss of vision; the eyes may be red, sparkling, or rolling rapidly. In such cases, the respiration will be more or less impeded, the skin hot, the appetite lost, the bowels confined, and the patient will repose on the side or back, and there may be convulsive twitchings of the extremities, and the thumbs flexed on the palms of the hands, with the fingers firmly clenched over them. This train of symptoms will be observed in hydrocephalus, during teething, and in certain dis-

eases of the bowels. When the process of dentition has caused it, the infant will put its fingers and every substance it can to its mouth, there will be tumefaction, or swelling of the gums, and a copious flow of saliva.

When the *lungs, or air-passages*, are inflamed, there will be fever, cough, and difficult respiration, and the exact tissue, or part affected, can only be discovered by the stethoscope, or auscultation, with the aid of percussion. Cough is a symptom of a multitude of different diseases of the respiratory organs, and prescribing for it alone is doing the patient a great injury, and in many cases, allowing his life to be sacrificed. There are some few old-fashioned practitioners who decry auscultation, because they are too lazy to study it, and others, who are incapacitated by defect of hearing, but there is no really scientific member of the profession, of the present schools, but will admit, that the discovery of the stethoscope has been one of the greatest ever made. I rejoice to add, that most of our Examiners in the Medical Corporations require candidates for diplomas to be well acquainted with auscultation. When the *alimentary canal*, including the stomach and intestinal tube, are irritated or inflamed, the infant will flex, or bend, its lower limbs on the abdomen, there will be heat of skin, pain on pressure of the abdomen, furred tongue, a brownish fur on the lips, picking of the nose or lips, disinclination for food, sometimes vomiting, desire for cold drinks, depraved motions from the bowels, and a vitiated condition of the urine.

The junior practitioner must remember, that the number of respirations in a minute, made by a young infant, are 35 or 40, double that of adults, and the pulse is from 130 to 140 during the first year, and hence little reliance is placed on this last diagnostic. The indications of diseases, given in the preliminary part of Dr. Hooper's Physician's Vademecum, 1833, will afford considerable assistance to the junior practitioner in the diagnosis of infantile complaints.

TRANSLATION OF M. ALIBERT ON THE DISEASES OF THE SKIN.

BY SAMUEL PLUMBE, M.R.C.S.

Late Senior Surgeon to the Royal Infirmary for Children, &c.

Dermatoses Eczematoses.—SPECIES II.

Erysipelas.—This inflammation shows itself on the surface of the integuments, chiefly on the face, arms, and thighs, but other parts of the body are not exempt, by a yellowish-red colour, and but rarely of a deep red. The redness disappears on the pressure of the finger. There is heat, and a painful sense of burning and itching. The febrile symptoms occur at first in some cases, but secondarily in others. It terminates

by desquamation or the formation of scurf, on the twelfth or fourteenth day in simple cases, but more serious results often follow.

There are three species of erysipelas. The simple, the phlegmonous, and the oedematous.

The simple form we have already defined.

The phlegmonous is marked by a double inflammation of the skin and subjacent cellular tissue. This form chiefly appears on the face, the cellular structure here being more vascular and delicate. It also very often attacks other parts of the body. In this form the patient encounters the double risk of phlegmon and erysipelas. There is a throbbing sensation in this form which is not experienced in the simple; the heat may be even less ardent.

The oedematous form is commonly known by the term white erysipelas. The skin is struck with atony, and presents a softness to the finger in pressing it, and retains the form of the substance applied to it. The colour of the skin partakes of a livid redness. The disease occupies at once the cutis and the subjacent cellular structure, into which an effusion of serum takes place. There is little redness or heat of the skin, but the tumefaction is very considerable.

General Remarks.—Erysipelas has received a multitude of names. Van Helmont termed it fiery abscess. Others gave it the names *rosa Anglicana*, *ignis sacer*, *ignis Persicus*, *ignis sylvestris*, *ignis Sancti Antonii*, &c.; all of which have been applied to other diseases. Very trifling diseases obtain these names from day to day.

Erysipelas is a very common disease, which occasionally shows itself at all periods and in all places. It not only attacks the human race, but shows itself among our domestic animals. Sheep are subjected to it, and in them it shows itself on the belly or chest, is often of a malignant kind, and sometimes ends in gangrene.

Erysipelas is not merely a disease confined to the skin. Bichat has shown the aptitude of the integuments to be attacked by it. It may fix itself in the coverings or linings of vital organs.

Simple Erysipelas.—SPECIES I.

The precursory symptoms of the disease are common to other forms of cutaneous affections. Nausea, bitter taste in the mouth, anxiety and

restlessness, headach and heaviness, starting in sleep and oppressive internal heat, a frequent and hard pulse, giddiness and disposition to delirium, also symptoms denoting a bad state of the first passages, and if the disease attacks the face the drowsiness is increased.

The inflammation afterwards concentrates itself on a particular point, and here the integuments are particularly swollen and distended, and are of a reddish lemon colour (*rouge citronné*). The skin is shining and smooth; and if the pressure of the finger disperses the redness, the latter instantly returns. The patient experiences a sharp burning sensation; but, after some time, this is changed to itching, and the inflammation declines. The cuticle is raised, as if by the action of a blister, it breaks, detaches, and separates itself, and a yellow serum flows from the part, becoming dried and attached to the surrounding epidermis. The disease has been always found most dangerous when attacking the head, from its proneness to spread to the membranes of the brain; and some have entertained the notion, from the circumstance of delirium accompanying the early stage, that the disease even originated in the membranes covering the brain.

We now stop, after describing the disease in its simpler forms. The disease may increase gradually during three or four days; we then see it stationary for twenty-four hours. Then come the periods of its subsidence and termination. When the redness continues for an indefinite period afterwards, vesicles occur from time to time, containing a clear limpid fluid, often sufficiently viscous to dry on and adhere to the skin. Subsequently, again, the contents of the vesicles become yellow, and the same process of desiccation takes place. It is probable, in this case, that deeper seated inflammation continues to go on, and furnish the discharge from the surface.

I cannot correctly state the precise period when the disease arrives at vesication. It is uncertain, and so is the duration of the attack altogether. In milder cases it disappears gradually. Sometimes it goes through its progress in the space of two or three days with the assistance of spontaneous perspiration; sometimes it continues twelve or fifteen days without diminution. Now and then it degenerates into gangrenous ulcers: this termination is very uncommon, notwithstanding

the livid tint which the skin sometimes assumes between the sores. The livid appearance usually vanishes as the constitutional symptoms improve in character.

Erysipelas, more or less intense, presents various characters, according to the part of the body it attacks. The slightest cases are those where it attacks the extremities. The febrile symptoms in such cases are slight, and amount to nothing. The inflammation spreads in a mild manner, the sensations of heat, itching, &c., are comparatively mild, resembling the sting of the nettle. It is generally little to be feared, but sometimes the suffering is great. If it occurs on the foot it spreads rapidly to the leg, to the integuments of the tibia, and there is great tenderness on pressure of these parts, which are distended and inflamed.

I have alluded to a form of erysipelas, which some German authors have qualified by the epithet—“*de foudroyant*” (*erysipelas syderans*). Dr. H. de Chégoni has seen lately a serious case of this kind in a man fifty-five years of age, a mason, occupied in his trade, repairing the vaults for the dead, in the Hospital “Du Val de Grace.” At the termination of his work he felt himself attacked suddenly; one of his legs and one of his arms were attacked at the same time. There were no febrile symptoms, but the appearance of the skin was frightful and malignant. His urine passed involuntarily, and other symptoms of a most alarming kind immediately followed. The eruption took on a livid appearance, and in the course of the next day the patient died.

Erysipelas attacks the mammae of females, and is commonly accompanied with much pain and suffering. The breast is red and swollen, and sometimes suppuration takes place; and if, as is the case in all glandular affections, this does not occur, induration of the parts and much inconvenience result, these organs remaining in an indurated state for a long time. Dr. Baron has observed cases of erysipelas in infants, commencing at the umbilicus and extending over the abdominal region. Sometimes it arises in the neighbourhood of the genital organs, and accoucheurs say it exhibits a tendency to gangrene. Dr. Billard thinks, in such cases, that it depends on disorder of the first passages, and is very often complicated with enteritis.

Phlegmonous erysipelas is, according to our author, the second form of this disease. It is a double malady, comprehending the symptoms of erysipelas and phlegmon alike. Like the preceding, it may occur in every part of the body, because there is everywhere cellular tissue. Those parts where the distribution of nerves is most liberal are most frequently its seat. Hence the face is so frequently attacked. The thorax and abdomen are next in succession as most likely to suffer from it. Simple erysipelas has usually less dependence on disorder of the gastric functions than this. The symptoms of the latter, in this form, consist of great nausea and vomiting. There is more constitutional disturbance, and the painful sensations in the seat of the inflammation are much aggravated. The febrile action is proportionably more violent and approaching more completely to those indicating the formation of matter.

The two forms are easily distinguished. The phlegmonous exhibits a more intense redness; the skin is more elevated, and resists more completely the pressure of the finger. Every thing shows that the inflammation is deeper seated, the pain becomes circumscribed, the heat is excessive and pungent, and lancinating pains are felt. The pulse is hard and frequent. Resolution sometimes takes place about the fifth day, but more commonly suppuration results. In the latter event, shivering and throbbing in the part give notice of it, and the matter should be discharged by puncture. But the termination of phlegmonous erysipelas is not always so favourable. It may happen that the inflammation extends to deep-seated parts under the aponeurotic expansions from muscles, and between the bodies of the latter, and when this occurs, the suppuration extends so considerably that it would be of no advantage to the patient. The surrounding parts are painfully distended, the sufferings of the patient are redoubled, and all the symptoms increased; the pulse is hard and small, and by itself denotes the danger of the case, the bulk of the matter increases, the muscles are separated from each other by the suppurative process*, the skin, especially deprived of nourishment, collapses; its connexion with the subcutaneous structure, being totally de-

stroyed, it becomes of a bluish hue, and when the case is of long continuance, the patient, worn out by diarrhoea, colliquative sweat, and hectic fever, dies a martyr to the disease.

Diseases of other kinds may take place from the effects of this. When low fever accompanies it, the patient dies in a short period from mortification, preceded by the usual symptoms of that event. Sometimes it wears an epidemic character, as in the instance where it desolated Toulouse in 1710.

Phlegmonous erysipelas is especially to be feared when it attacks the head; a red spot first shows itself, spreading very soon over the neck and scalp. A patient presented himself with a painful spot on the left ear, it was followed by active inflammation and severe headach. Three days after, the first affected spot was punctured, and matter discharged, but the surrounding inflammation extended itself. Several pustules formed on the other parts of the head. We attempted to promote suppuration by poultices and fomentations, but the patient died from metastasis to the brain, where matter was found in considerable quantity, on examining the body after death. The great danger of these kinds of erysipelas depends on their disposition to attack the brain.

Œdematous Erysipelas at its commencement scarcely ever shows itself in a form deserving the name of this disease. It is the consequence of another disease, and is formed by the effusion of fluid into the cellular tissue. Breschet has shown its analogy to dropsy of the cellular membrane. Schroeder had made the remark before. In St. Louis I have observed that this form of the disease is accompanied with some heat of skin, and redness, and pain. There are phlyctenæ formed occasionally, but not so distinct as in the other forms of the disease before mentioned. In cases of scurvy similar phlyctenæ occur of a blue colour and containing bloody serum.

In calling this affection a form of erysipelas, we have said that the skin is weak and without the power of resisting the pressure of the finger, but it is in other cases hard and unyielding.

As belonging to this division I venture to class a disease which I have described elsewhere which seemed to be for a long time not understood. I allude to the *sclérmie* of new-

* Les muscles se séparent de leurs points d'appui.

born children. M. Gardien has confirmed my ideas, he witnessed a case where it ended in suppuration.

“Concrete œdema,” and “d’erysipèle dur des petits enfans” are the terms used to designate this disease by M.M. Souville, Baron, and Billard. We know that venous blood is essentially concerned in producing morbid fulness of vessels, and that at the earlier periods of life, the skin and cellular tissue are sometimes too copiously supplied. The suddenness of the exposure of the skin of the new-born child to the atmosphere, is often followed by inflammation which does not, from the weakness of the subject, very suddenly show its usual characteristics. It assumes first the appearance of the œdematous erysipelas. It is sometimes marked by red or bluish patches on the surface, dryness of the skin, and the absence of perspiratory moisture; sometimes there is desquamation of the cuticle, but there is always evidence of the existence of fluid in the cellular tissue. There is now under my observation, in a man who has been subject to it in a wandering form, a similar disease. It made its first appearance near the ankle of the left leg, from which it gradually extended along the leg and thigh on the same side. Other parts of the skin afterwards evinced it, and the patient became much alarmed. Both the lower extremities presented an ivory hardness, the skin is of a pale red and shining appearance in every part which is attacked.

Erysipelas is in its first attack and progress very insidious, and apt to return with violence when the patient appears to be on the high road to recovery.

The Etiology of Erysipelas.

To investigate thoroughly this part of the subject, we must attentively look at its different seats at its commencement. We have already said that it takes place in the vascular structure of the skin. The vessels of the surface are the evident seats of the disorder in the first instance, from the increased heat and redness which precede other and severer symptoms. Their exposed distribution explains this; deleterious agents of all kinds, mechanical and chemical, are constantly affecting them. The analogy between erysipelas and the other forms of disease, under the head D. eczematoses, fully entitles it to the place we have assigned it; it is from its

characteristics entitled to the first rank. Young men are most frequently the subjects of it, and those of plethoric habit of body. It often follows suppressed hæmorrhages, or discharges which have been exercising beneficial effects on the system. Stahl and his school have particularly noticed this fact. The suppression of the menstrual fluid or the discharge from hæmorrhoids often produces it. Exposure to the heat of the sun or the frosty air of a severe winter, certain habits of life, as those of the epicure, who freely indulges in stimulating diet and wines, are powerful predisposing causes.

Poisonous or irritating substances, taken into the stomach or externally applied, exposure to a burning sun, the acid juices of plants, such as the *rhus toxicodendron*, &c. In short, it may be produced by thousands of circumstances.

The most formidable forms are those which follow gun-shot wounds, and those which attacking the head spread to the membranes of the brain. Particular trades, those always being such as compel exposure to heat on the part of the artizan, produce the greatest number of instances. Emotions of the mind sometimes appear to be a cause. In one instance a criminal, sentenced to death, had his life prolonged for forty days by its timely visitation.

Treatment of Erysipelas.

This must depend on a serious consideration of the situation and circumstances of the patient. Bleeding is necessary where fulness of habit exists, and the pulse is hard and full and other signs of power and excitement show themselves. Leeches to the interior of the nose are to be recommended where the head is affected, and all other measures calculated to empty the vessels of the head. The discernment of the practitioner is the only legitimate guide, for signs of debility may exist when opposite measures may be called for. Emetics are useful, for the disease often arises from disorder of the *primæ viæ*. A bilious habit generally exists. Emetics were found most useful by Desault and Stoll of Vienna. Tartar emetic is the best form in a state of solution, the disturbance it creates in the alimentary canal is always found beneficial. Copious diluents, ptisanes of different and simple materials are requisite. External applications consist of cataplasms or emollient fomentions.

tions. In the phlegmonous form incisions are necessary to allow of the discharge of matter.

Foreign Medicine.

On the Causes and Treatment of Icterus.

ACCORDING to M. Piorry, the obstruction to the passage of the bile may be situated, first, in the liver; second, in the great trunk of the hepatic duct; third, in the ductus communis choledochus; fourth in the intestines; for these may be considered as an extension of the biliary ducts, and the constipation, which occurs in them, is one of the causes of icterus, since it determines the stagnation of bile in the canals from which it is absorbed.

Bile in icterus, or at least its colouring principle, is contained in the blood. It is true that M. Deyeux has not found it in one case, but M. Orfila has met with it, and according to others simple inspection demonstrates the fact. At first (as in the case of jaundice mentioned in No. 109), the serosity of the blood is yellow, and afterwards that produced by blisters, perspiration, and the urine is coloured with the same. In many cases, in patients who have suffered from icterus, M. Piorry has found the bronchial discharge yellow, and in the case above alluded to, the saliva was green; the colourless tissues, such as the sclerotic, become yellow, the skin also participates in the same colour, whilst, on the contrary, the fæces are discoloured. Thus the stagnation of the bile in its reservoir, or the disappearance of this fluid into the successive portions of the excretory canal, and lastly, the presence of the yellow ingredient in the fluids and solids, offers, according to the author, sufficient proof that it is the bile which is thus scattered throughout the whole system. To say that jaundice may be compared to ecchymosis, is to make use of an analogy which is deceitful, and does not enter properly into the merits of the case; and to suppose that the bile can be formed before its arrival at the liver, is to use an hypothesis which is not in accordance with that which we see in a great majority of cases. Pursuing these inquiries, M. Piorry considers that the following are the indications to which, in treating the disease, the attention should be principally directed: 1st. To inquire into the nature and seat of the obstacle which causes icterus; and here he

recommends bleeding if it depends upon hypertrophy of the liver, purgatives if the cause be constipation, and leeches if the duodenum be inflamed, as in the cases cited by M. C. Broussais. 2nd. To dilute the bile with water, for the purpose of facilitating its flow, and the escape of calculi if any such exist. 3rd. To give large quantities of fluids to remedy the existing icterus.

He adds to these drinks saline purgatives, or diuretics; and another case of icterus, in ward St. Landry, has since yielded not less promptly than the one before alluded to, under treatment founded on the above indications.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

By-Laws relating to the Examination of Candidates for Letters Testimonial or the Diploma.

[THE following regulations, with regard to the preliminary and medical education of surgeons, are infinitely superior to those required by the Royal Colleges of Surgeons in London and Edinburgh, or the Faculty of Physic and Surgery in Glasgow; and ought to be immediately adopted by the institutions just named. Candidates for the diploma or letters testimonial of the Dublin College, undergo several examinations in ALL the medical sciences, (not merely in anatomy and surgery at half an hour's sitting, as in London,) and must be really well acquainted with medicine in all its branches. Moreover they generally become graduates in physie, and are eminently qualified as physicians and surgeons. The midwifery diploma is another improvement, which the London, Edinburgh, and Glasgow corporations should grant as soon as possible. "Nunquam sera est, ad bonos mores via."—*Ens.*]

Half Yearly Examinations.

I. The president, with the vice-president and the members of the Court of Censors and Assistants, or a majority of them assembled together, shall appoint, by a majority of voices from among themselves, four or more members, with the president or vice-president, to examine the registered pupils as to their proficiency in their studies, every half year, in the months of May and November, of which examinations due notice shall be given by sum-

mons, and by advertisement in the newspapers.

II. The pupils shall be divided into four classes, and each class shall be examined in the presence of the members and licentiates of the College, for such length of time, not being less than one hour, as the Examiners may think proper, and the name of every pupil, who shall answer such examination to the satisfaction of the said Examiners, shall be enrolled by the secretary in a book provided for that purpose.

III. The first class shall be examined as to their knowledge of the principles of physiology, the descriptive anatomy of the bones, ligaments, muscles, and joints, the first principles of surgery, and elements of Chemistry.

IV. The second class shall be examined as to their knowledge of the anatomy and physiology of the vascular and respiratory organs, including the descriptive anatomy of the heart and lungs, and the relative and surgical anatomy of the arteries and veins, of the nature and surgical treatment of wounds in general, hæmorrhage, fractures and dislocations, and of the practice of pharmacy and the materia medica.

V. The third class shall be examined respecting their knowledge of the general composition of animal structure, the anatomy and physiology of the organs provided for digestion, chyfication and secretion in general, including the structure of the skin and mucous membranes, and the descriptive anatomy of the abdominal viscera and absorbents, of tumours and diseases of the bones and joints; of pathology, and the principles and practice of medicine in general, and the nature and treatment of febrile and inflammatory diseases in particular.

VI. The fourth or senior class shall be examined respecting their knowledge of the anatomy, physiology, and pathology of the brain and nervous system, and of the organs of sense, and the urinary and genital organs, of injuries of the head, and of operative surgery and medical jurisprudence.

VII. Candidates shall be liable to be examined respecting their knowledge of any of the preceding subjects, or of any other subject not here enumerated, at their final examination for letters testimonial, as heretofore.

VIII. Pupils who become candidates for

letters testimonial, subsequent to the 1st of January, 1835, shall be admitted to examination for such letters testimonial, if they shall have passed a half yearly examination in the fourth class.

IX. Pupils who become candidates for letters testimonial, subsequent to the 1st of January, 1836, shall be admitted to examination for such letters testimonial, if they shall have passed a half yearly examination in each of the third and fourth classes.

X Pupils who become candidates for letters testimonial, subsequent to the 1st of January, 1837, shall be admitted to examination for such letters testimonial, if they shall have passed a half yearly examination in each of the second, third and fourth classes.

XI. Pupils who become candidates for letters testimonial, subsequent to the 1st of January, 1838, shall be admitted to examination for such letters testimonial, if they shall have passed a half yearly examination in each of the first, second, third and fourth classes.

XII. The Court of Censors shall be authorised to examine candidates for letters testimonial, who have been unable, in consequence of absence from Ireland, or some other equally excusable cause, to answer the half yearly examinations required by the above by-laws; and the discretionary power vested in the Court, respecting the examination of candidates who commenced their education previous to the 1st of January, 1829, is not repealed or altered by these by-laws.

Examination for Letters Testimonial.

XIII. Every registered apprentice shall be admitted to an examination for letters testimonial, if he shall have passed the half yearly examinations required by the by-laws, and if he shall have laid before the Court of Censors the following documents:

1. A certificate signed by the president or vice-president and two of the censors, that he has passed an examination as to his acquaintance with the Greek and Latin languages in the following books: viz., the works of Sællust, the first six books of the *Æneid* of Virgil, the Satires and Epistles of Horace, the Greek Testament, the Dialogues of Lucian, selected by Walker, and the first four books of Homer's *Iliad*; or a

certificate from his tutor that he has entered as a student into Trinity College*.

2. His indenture of apprenticeship, regularly registered, with a certificate signed by the member or licentiate to whom he has been indented, that he has fully and perfectly served such apprenticeship for the full term of five years.

3. A receipt showing that he has lodged to the credit of the President, and for the use of the College, in the Bank of Ireland, the sum of thirty guineas.

4. Certificates of attendance on three courses of lectures on anatomy and physiology, three courses of lectures on the theory and practice of surgery, and the performance of three courses of dissections, accompanied by demonstrations; also, certificates of attendance on two courses of lectures on chemistry, one course of lectures on materia medica, one course of lectures on the practice of medicine, one course of lectures on midwifery, and one course of lectures on medical jurisprudence; with such certificates of attendance on the practice of an hospital or county infirmary as may satisfy the court that the candidate has had sufficient opportunity of acquiring practical information.

5. A thesis, essay, or dissertation in Latin or English, fairly engrossed, according to a prescribed form upon any of the following subjects:—anatomy, physiology, surgery, practice of medicine, chemistry, materia medica, midwifery, or medical jurisprudence; or, in place of such dissertation, a series of cases collected in the hospital in which the candidate has attended, illustrated by comments or observations.

XIV. Every candidate who has not served an apprenticeship shall be admitted to an examination for letters testimonial, if he shall have attended lectures or hospitals for three winter seasons, at least, in Dublin, London, Glasgow, or Edinburgh; if he shall have answered the half-yearly examinations required by the by-laws; and if he shall have laid

before the Court of Censors the following documents:—

1. A certificate signed by the president or vice-president, and two, at least, of the censors, that he has passed the examination, as to his proficiency in the Greek and Latin languages, as prescribed for the registered apprentices, or a certificate from his tutor that he has entered Trinity College.

2. A receipt, showing that he has lodged to the credit of the president, and for the use of the College, in the Bank of Ireland, the sum of thirty guineas.

3. Certificates showing that he has been engaged in the study of his profession in some hospital or school of surgery or medicine, for the full term of five years.

4. Certificates of attendance on a surgical hospital containing at least fifty patients, during five winter seasons of six months, or three years, if such attendance shall not have been perfected during the winter seasons.

5. Certificates of attendance on three courses of lectures on anatomy and physiology, three courses of lectures on the theory and practice of surgery, and the performance of three courses of dissections, accompanied by demonstrations; also certificates of attendance on two courses of lectures on chemistry, one course of lectures on materia medica, one course of lectures on the practice of medicine, one course of lectures on midwifery, and one course of lectures on medical jurisprudence.

6. A thesis or series of cases as enjoined for registered pupils.

Examinations of Candidates for the Midwifery Diploma.

XV. The mark, distinguishing practitioners in midwifery in the printed lists of the College, shall not be affixed to the name of any member or licentiate of the College, unless he shall have obtained the license or diploma of the College authorising him to practise that branch of surgery, as hereinafter specified; or unless he shall have received some recognised midwifery diploma, previous to the 1st of May, 1831.

XVI. A Court of Examiners, consisting of a chairman, deputy chairman, and six members, shall be elected by ballot, on the first Monday in January in each year, to examine

* The tutor is one of the Fellows of the University; and the person obtaining his certificate, must have passed a more extensive classical examination than that of the College of Surgeons.—Eds.

such members or licentiates as become candidates for the diploma in midwifery; any four of which Court, with the chairman or deputy chairman, shall be competent to hold such examination.

XVII. Every candidate for the diploma in midwifery shall be admitted to an examination, if he shall have laid before the Court the following documents:—

1. A receipt, showing that he has lodged to the credit of the president, and for the use of the College, in the Bank of Ireland, the sum of five guineas.

2. Certificates of attendance on two courses of lectures on midwifery, of three months' duration each, or one course of six months'.

3. A certificate of attendance on an established lying-in hospital for a period of at least six months, or a certificate that he has been a resident pupil for six months in some established dispensary for lying-in women, and diseases of women and children, devoted to this branch of surgery alone, such hospital or dispensary to be approved of and sanctioned by the Midwifery Court.

4. Satisfactory evidence that he has conducted thirty labour cases at least.

XVIII. Candidates for the midwifery diploma shall be examined on the anatomy and physiology of the female generative system, the theory and practice of midwifery, and on the diseases of women and children; and if approved of by the Court, shall receive a licence or diploma to that effect, to which the College seal shall be affixed. Should a candidate be rejected, he shall not be again admitted to an examination until a period of three months shall have elapsed, and he shall then be obliged to produce satisfactory evidence of his having been engaged in the study of this branch of surgery subsequent to such rejection.

General Regulations.

XIX. No certificate shall be received for attendance on lectures delivered in Ireland, unless from teachers in schools permitting the visitation of the Court of Censors, and receiving their sanction. Neither shall certificates be received from teachers or professors in colleges or other institutions for medical or surgical education in Great Britain or Ireland,

which colleges or institutions refuse to receive, as qualification for a degree or license, the certificates issued by professors in the College of Surgeons.

XX. No certificates shall be received from teachers who deliver lectures upon more than one distinct subject, as hitherto allotted to professors in colleges in universities. This regulation shall not, however, exclude the certificates of two or more teachers who deliver conjointly, separate, perfect, and distinct courses on anatomy and physiology, and on the theory and practice of surgery.

XXI. No certificate shall be received for attendance on lectures on anatomy and physiology, unless such lectures shall have been delivered upon at least five days in each week of the usual winter session, between October and May; nor on the theory and practice of surgery, unless delivered within the same period, on at least three days in each week. The two courses delivered in London, and there called autumn and spring courses, shall, however, be considered equivalent to one winter course of six months, as delivered in Dublin and elsewhere.

XXII. Every candidate presenting certificates of attendance on lectures or hospitals, previous to his examination for letters testimonial, shall be liable to be examined respecting their authenticity; and if he shall refuse to answer thereupon, or if it shall appear from his answers, or from any other information obtained by the Court of Censors, that he has not attended such hospital or lectures with regularity, or according to the regulations laid down by the College, or for the full time stated in such certificate, he shall not be admitted to an examination for one year; and should it be proved that he has presented a forged certificate, or a certificate obtained by causing some person to personate him, and attend for him, he shall never be examined; and if such fraud shall be discovered, after the candidate shall have obtained letters testimonial, he shall be expelled, and such letters shall be withdrawn, and shall be given up by him to the College, on demand in writing, signed by the secretary, or in default thereof, proceedings shall be had against him on his bond.

XXIII. The examination of every candidate for letters testimonial, shall be held in the presence of the members and licentiates of

the College, or such of them as choose to attend, and the secretary shall, by regular summonses, give at least four days' notice of such examination.

XXIV. Every candidate for letters testimonial shall be solemnly examined on two several days in anatomy and physiology, in the theory and practice of surgery and medicine, in chemistry, and in the materia medica; candidates shall be expected to perform such surgical operations, or make such dissections on the dead body, as the Court of Censors may require; or they shall be called upon to explain any anatomical preparation which the examiner may lay before them.

XXV. In case a candidate shall be rejected, and shall appeal to the Court of Assistants, such appeal, stating that he considers himself aggrieved by the decision of the Court of Censors, shall be lodged within eight days from the date of rejection, and the candidate shall be submitted to examination within fourteen days from the date of such rejection. The examination before the Court of Assistants shall be conducted in every respect as the examination before the Court of Censors.

XXVI. A candidate for letters testimonial, who shall have been rejected, shall not be admitted to another examination, except upon his appeal, in less time than one year from such rejection, and he shall then be required to lay before the Court satisfactory evidence of his attention and opportunities of improvement, subsequent to the period of his rejection.

XXVII. The Court of Censors shall be authorised to examine candidates for letters testimonial who have not been educated in strict conformity with the above by-laws, but who shall produce evidence of having received a professional education equivalent to that required by the College, provided such candidates shall have commenced their professional education previous to the 1st of January, 1829. The Court shall also be authorised to receive certificates issued by competent teachers previous to the 1st of May, 1829, notwithstanding any regulation to the contrary in the above by-laws.

APOTHECARIES' HALL OF IRELAND.

Notice of Qualification required from Candidates for Examination.

The Court of Directors and Examiners of

Apothecaries' Hall of Ireland, in pursuance of an act of parliament, passed in the thirty-first year of the reign of his Majesty, George the Third, entitled "an Act for regulating the Profession of an Apothecary throughout the Kingdom of Ireland,"

For Certificate of Apprentice,

1st. Resolved, that persons seeking to become qualified to be apprenticed to the profession of an Apothecary, shall produce testimony of being fifteen years of age, and shall undergo an examination in Latin, comprising the following Books:—the first six Books of the *Æneid* of Virgil, the *Cataline* and *Jugurthine War* of Sallust, and the *Odes*, *Satires*, and *Epistles* of Horace; in Greek, the *Gospel of John*, *Dialogues of Lucian* (Walker's edition), and first three Books of Homer.

For Diploma of Licentiate.

All Candidates for the Diploma of Licentiate of the Apothecaries' Hall of Ireland, shall submit to the Court the following testimonials of qualification, four days previous to examination:—1st, the certificate of permission to be apprenticed, obtained at former examination. 2nd, Indentures of apprenticeship, for seven years, to a Licentiate of Apothecaries' Hall of Ireland, with a certificate from said Licentiate, that the period has been duly served, also of moral conduct. 3rd, Certificates of having attended at least one course of lectures on each of the following subjects:—chemistry, materia medica and pharmacy; botany, practice of medicine, anatomy, and physiology. The certificates of attendance upon lectures received by the Court of Examiners as qualifications are expressed as follows:—

Chemistry, Materia Medica, and Botany.

—By Professors to Universities, by the Professors to Apothecaries' Hall, or by Lecturers in the approved Schools in Great Britain.

Practice of Medicine.—By Professors to Universities, Professors to Apothecaries' Hall, or by Lecturers in the approved Private Schools of Great Britain and Ireland.

Anatomy and Physiology.—By Professors to Universities, Professors to Royal Colleges, or by Lecturers in the approved Private Schools in Great Britain and Ireland.

Each course on chemistry, materia medica, and pharmacy, practice of medicine, anatomy and physiology, to consist of not less than

sixty lectures, and on botany not less than forty.

By order of the Court,
WILLIAM MADDEN, Sec.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, March 1st, 1834.

Dr. GREGORY in the Chair.

Paraplegia without Disease of the Spine.—

Diagnosis of Disease of the Brain.—Strychnine in Paralysis, Hysteria, Dyspepsia, and Neuralgia.

A QUESTION asked by Mr. Costello, with regard to the subject of petitioning Parliament for Medical Reform, led to some discussion on this topic; after which, some time having passed in solemn silence,

Dr. Gregory related the following case, which had lately fallen under the notice of Mr. Turnham, the Secretary, and which appeared of great importance, since it went far to confirm the opinion of Dr. Baillie, in regard to the existence of paraplegic symptoms without disease of the spinal cord. This case was one of paraplegia existing independent of injury to the spinal marrow.

Charlotte Smith, aged 10, of 8, Upper Rupert-street. Her father is a healthy man, of good constitution, has been twice married; by his first wife he had a family of healthy children; his present wife appears, however, to possess a strumous diathesis; her offspring are all the subjects of some disease; one labours under the effects of rachitis, one has died of epilepsy, to fits of which two are still subject. The subject of the present narrative was possessed of good health up to her eighth year, was a child of amiable disposition, and was very attentive to those studies to which children of her age and condition are usually directed. Her father was, however, induced to remove her from school, in consequence of perceiving a growing languor, both of body and mind, and from her complaining of severe headach. These symptoms, and others of an insidious character, continued for about a twelvemonth, when they became aggravated, and a strabismus of both eyes coming on, induced her father to apply for relief at the Westminster General Dispensary, where she

was admitted as a patient under Dr. Granville, during the winter of 1832. He ordered leeches to the head, with a mercurial aperient, and wrote on the letter that there was disease of the cerebellum. A month or two after this she was transferred to Dr. Davie, who requested me to attend to the case for him, which I did from that time to her death. The strabismus had then merged into complete amaurosis, the pupil being excessively and permanently dilated, and insensible to the strongest light; voluntary motion and sensation became gradually impaired in the inferior extremities; and these symptoms becoming aggravated, the result was a perfect paraplegia; the urine and feces were now, and until her death, passed involuntarily; the former of these excretions was remarkably foetid. There was a partial paralysis of the upper extremities; but this never became complete, indeed they were the subjects of occasional slight convulsions. The pain in the head was much increased in violence, particularly in the region of the occiput.

The treatment, adopted by Dr. Davie, consisted of blisters behind the ears, kept open by savine cerate, leeches repeatedly applied to the temples, and an evaporating lotion to the whole head, as well as calomel and jalap internally at least twice in the day. These remedies were continued for several months, with greater or less regularity, without the least improvement, as, in spite of them, the violence of the symptoms increased. Convulsive paroxysms, in which she suffered the greatest pain, now attacked her at intervals of various durations, her sleep not unfrequently being molested by them; at other times she lay in a remarkably quiet state, a placid smile being constantly observable on her countenance. Throughout her illness the circulating and respiratory systems were but little affected, nor were the nutritive functions impaired. A fortnight before death she was attacked with a convulsive fit of longer duration than usual, after which a comatose state ensued, which lasted for two or three hours; on her recovery from this condition her appetite was lost, and she gradually sunk till the 14th of Dec. 1833, when she suddenly but quietly expired.

Autopsic examination, forty hours after death.—Upon opening the cranium and removing the hemisphere of the brain, the roots of the lateral ventricles were found to be en-

traordinarily elevated, and showed, through their semi-transparent substance, the presence of a large quantity of fluid, which soon escaped, to the amount of six or eight ounces. The cavities of the anterior and posterior cornua of the ventricles had become remarkably apparent, from the distending effects of the fluid. In the posterior left lobe of the cerebrum there was a mass of caseous scrofulous matter, about the size of an egg; it was situated in close contact with the pia mater. The cerebellum was also found to be almost entirely in the left, and to a very great extent (about half) in the right lobe, converted into the same substance. Upon being cut into, this was found to be of a much firmer and denser consistence than is possessed by the healthy structure of the brain, and to be of a dirty yellow colour. Upon elevating the base of the brain, it was detected that the arachnoid and pia mater, in this situation, were much thickened, and rendered opaque by the organisation of much effused fibrine, in which the roots of the nerves were involved. The optic nerves appeared to be much softer than in their normal condition. The spinal cord was remarkably healthy, nor did its membranes possess any marks of unusual vascularity.

In the *thorax*—the heart and its appendages were healthy; the lungs had some small vomices, more particularly at their summits.

In the *abdomen*—the liver was remarkable for its large size, and almost equal development on both sides of the body. In its substance, as well as along the course of the colon, were numerous cysts, filled with scrofulous matter, much softer however than that in the brain. The tissue, both of the uterus and ovaries, was converted into the same soft caseous-like matter, with which the cavity of the former was completely filled. The kidneys and other viscera were healthy.

Mr. Costello wished to place by the side of this case one which seemed to resemble it, since, although the inferior half of the body was in a complete state of paralysis, yet, on examination, no lesion of the medulla spinalis was found. A man, æt. 42, of spare habit of body, about twelve months since, according to his custom, after beating his coat on the leads of the house, leaped down a few steps into the kitchen, which was the attic floor, when he felt something snap; a few hours after there seemed to be a slight pressure on the lumbar

region, which continued to increase; during the night he found that he had lost the use of his lower extremities, and that the power of expelling his urine was gone. He was bled by a surgeon, after which the bladder resumed its functions, but only for a short time. In the morning Mr. Costello saw him, and drew off his water. Issues were, after depletion, applied to the sides of the lumbar vertebrae, where the pressure, at first felt, had now changed to pain. A remarkable circumstance was, that this pain did not remain permanently fixed in any one spot, but gradually passed down from one vertebra to another, and, previous to his death, again ascended in the same gradual way. For a time his health seemed to improve, the emaciation, which was rapid, stopped, and his appetite increased; now, however, pus was observed in the urine, and, judging from this, and the circumstance of the patient's having two years before complained of pain in the lumbar region, together with the total absence of any irritation in the bladder, it was supposed that the presence of this secretion depended on some disease in the kidneys. The locomotive powers, for a time, slightly improved, but without being accompanied by any amendment in the sensitive organs. This improvement was, however, only delusive, for shortly afterwards the patient died suffocated. Mr. Brodie, by whom the case was also seen, thought that there would probably be found ramollissement of the cord; and, in answer to the objections of Mr. Costello, on account of the rapid appearance of the symptoms, adduced some cases of ramollissement occurring rapidly, related by Lallemand.

Autopsy.—The brain was perfectly healthy; the spinal marrow and sheath were injected, and, in the lumbar portion of the canal, clots of crassamentum adhered to the bones, whilst the serous portion of the blood floated; it was probably from the absorptions of portions of the blood that the pain in this region was to be accounted for; there was no ramollissement in any part of the canal, and the substance itself, independent of the injected state, appeared healthy.

Dr. Johnson said, there could be little doubt but that there could be extreme disorder of function, which might even amount to paralysis, without leaving any permanent structural disease; it was not uncommon to find paralytic

symptoms in children lasting a short time and then suddenly disappearing, and in such cases it was not possible to suppose that permanent disease existed in the brain.

Dr. Gregory said, that Dr. Baillie, with all his anxiety to establish this fact as a pathological principle, had never been able to meet with dissections proving the point.

Mr. Costello made allusion to the work of Cruveilhier, on the subject of Disease of the Brain, which he spoke of in high terms of commendation.

Mr. Johnson could not go to the length which Mr. Costello did in lauding this author; he did not think it always possible to predicate from the symptoms the exact situation of lesions of the brain; and, in illustration of this, he mentioned an instance in which lesions of, and effusions into, this organ were found after an injury, although there were no symptoms which indicated such disease.

Mr. Chinnoek did not think cases, similar to that mentioned by Mr. Johnson, in the least affected Dr. Baillie's theory, since, in the cases upon which the Doctor had founded his opinion, chronic disease had invariably existed. He quite agreed in what had fallen from Mr. Johnson in reference to M. Cruveilhier, and he was the more induced to do so from two cases which had fallen under his notice, in one of which, although paralysis exists and had existed some time, no appearance of disease or other symptoms of lesion could be discovered. He had been induced, in one case, to give strychnine, but from what he had seen of its merits, he certainly should not again make use of it.

Mr. Greenwood made some remarks on the value of pathological investigation. In speaking of strychnine, he thought it should only be applied where there was a torpid action of the brain.

A few observations on the difference between meningeal and general apoplexy having fallen from some of the members.

Mr. Chinnoek related a case of paraplegia, in which most of the eminent practitioners of London and Paris were consulted, and were unable to discover the cause of the disease, or any effectual remedy. Strychnine had been tried without effect.

Dr. Gregory referred to a case in which a patient, after taking strychnine, was affected with spasm of the tongue. From the expe-

rience in the medicine which he had had, he certainly should not be inclined any more to use it.

Dr. Ryan observed, that Mr. Chinnoek's case was not a fair one for strychnine, as it had defied all remedies, and was not sufficient evidence against the value of the medicine alluded to. He had tried strychnine in several cases of hemiplegia, dyspepsia, hysteria, chorea, and in a few patients affected with neuralgia, with the best effects. He thought the dose generally used was too large; he commenced with one-twelfth of a grain, and met no patients as yet who could bear more than five times that quantity without inconvenience. M. Magendie and Dr. Bardsley of Manchester had given it in much larger quantities. It was difficult to procure the medicine genuine. He placed the greatest confidence in it in disorders of function or purely nervous affections, such as those he had mentioned.

Dr. Gregory thought the remarks of Dr. Ryan, as to the administering small doses of the medicine, of importance. Some preparation, in which it might thus be more easily given in such small doses, was desirable.

Dr. Ryan said, in answer to a question, that it was in functional, not organic, disease that it should be prescribed.

A member wished to ask Dr. Ryan if he had used the alcoholic extract of *nux vomica*, and in what doses? In one case he had seen it used, when it produced symptoms of poisoning, which, however, went off after some hours.

Dr. Ryan replied in the negative. He said it was too much the custom of late years to expect to find the cause of death on autopsic examinations; and many seemed to forget the existence of a cerebro-spinal system in man. The question generally is, what are the morbid appearances? The numerous disorders of function, as frequent and as painful as lesions of structure, called for attention every hour, and if they proved fatal, no morbid appearances will be found on dissection. This was generally the case in the nervous disorders to which he alluded, though there were exceptions. In such cases strychnine in small doses would be found one of the best remedies. He had employed it in dispensary and private practice, in at least one hundred and fifty cases of various disorders, with the most astonishing success.

Mr. Greenwood was always sorry to hear any one rise and deprecate the pursuance of pathological investigation, to which we were so much indebted for our knowledge on most points.

Dr. Ryan rose to order, and wished to explain that no one felt more interest in pathology than he did, but he contended it should not be studied to the exclusion of therapeutical agents. We could not investigate the nature of diseases too much, nor should we neglect to enlarge our remedies. To the mere pathologist he would apply the axiom of Celsus—

“*Morbi non eloquentiâ, sed remediis curantur.*”

The meeting then separated.

POWER TO CONFER MEDICAL DEGREES IN LONDON.

BEFORE we resume our remarks of last week, upon the necessity of vesting the power to confer Medical Degrees in some body distinct from the existing Corporations, or any School of Medicine, and governed by different principles, we cannot but notice the delicate and ingenuous manner in which the same subject has been since treated by a cotemporary; and by exhibiting the naked form of his project, without the drapery his modesty has thrown over it, we shall enable the public to judge of his sincerity in this new guise it is his fortune to assume.

Since our last article was written, a report has been made to the proprietors of the London University, in which it is stated, that “the Council have not yet overcome the difficulties which impede their attainment of a charter of incorporation, but that they have taken measures to bring the subject before the Privy Council.” A charter has, of course, been eagerly sought for, ever since the first establishment of the University; and

when we consider that the bulk of its subscribers and supporters, however excellent subjects, are not exactly of the Church-and-State class, and that they cannot but be jealous of the *privileges* acquired by an University degree, and may have some desire to give their families a liberal public education, with all the advantages of eminent teachers and of unbounded competition, without sending their sons out of the kingdom;—it is not very atrocious that they should seek as liberal a power of conferring degrees in arts, as is possessed by the unrivalled orthodox universities—*sui amantes sine rivali*: and if these sentiments were not too bad in the reign of perfection before Reform, we cannot see why they should be stifled in the year 1834. A few years ago Medical Reform, upon general principles, was the dream of visionaries. All that is changed; and with it all mere palliations are now useless. But at the time we allude to it was not very unreasonable for the great interests, connected with the University, and severed by conscientious motives from the chartered establishments, to demand that the University of London might imitate its rivals at Oxford and Cambridge, in the power of conferring medical degrees: and objectionable as it would have been, for many reasons, to concede such a power in imitation of even the lordly Universities of England, there are evils it would have remedied. We are not in the secrets of the London University; as Journalists we have experienced the petulant discourtesy of one of its professors,—but we neither love nor hate; and, in our strictures upon its claims, we profess and hope to practise perfect impartiality. As to the general amount of its claims, to give degrees as a literary and scientific school, we know nothing: and indeed—medicine apart—except as concerns some privileges accorded to gra-

duates of the English and Irish Universities, on their admission to the legal profession, occasioned principally by the rules as to residence which are inapplicable to the London University, its degree can confer no advantage, honour excepted, not already conceded to it, since the Presbytery of Scotland have recognised its lectures. But the power of giving medical degrees it never can acquire. The times are now ripe for a more wholesome system of medical legislation; the whole state of the case is altered; the question with the University is no longer one of rivalry, but of existence; and the Government has now, not the power only, but the will also, to abolish altogether the monopoly of teaching, instead of palliating its evils by raising an additional privileged school to abuse, in its turn, its delegated trust. We firmly believe, that no influential person, connected with the University, whose opinions are worth considering, has harboured any such expectation since there was a probable chance, now happily realised, of a general investigation into the condition of Medical Education in the United Kingdom, with a view to its efficient reform. We have no secret source of information:—we believe it is well known, that the Lord Chancellor has turned his powerful intellect to the wants of the profession, and that his opinions, as to the proper remedy, are far from favouring the narrow project of relief we have been canvassing;—although there were not, at this moment, a Committee of the House of Commons sitting in judgment on our grievances, we think the deliberate caution, with which the application of the University has been received by the Privy Council, is sufficient warrant that nothing rash and inconsiderate, touching the profession, would be attempted under his Lordship's advice.

This notification of their proceedings

by the Council has elicited an article from our cotemporary, with an epigram for its title, and malice, envy, hatred, and all uncharitableness for its contents. When we hear of a "proposed University in London, not the London University," from the Medical Gazette, if we think of consistency, we may in vain ask—

"How can these contrarieties agree?"

and if the venom of the article attracts our notice, it is as vain to ask, who poisoned the shaft? seeing there are more than one engaged in the trade. Here is a specimen of the calumny with which a journal, under the patronage of the College of Physicians, asperses honourable men. It asserts that "some of the proprietors of the establishment in Gower-street have chosen the present moment again to step forward,—or rather to *steal with silent and noiseless tread*,—to the closet of the minister, and endeavour by *private solicitation* to obtain the boon they have so long coveted, and thus virtually to forestal the result of the parliamentary investigation, which is already in progress. True, this request is indicative of that *habitual modesty* which characterises all their proceedings, &c., &c., &c." Again, even Parliament is disqualified from legislating touching a charter at all, because "no inconsiderable number of those who will be called upon to legislate are actually proprietors of the institution which it is intended to benefit, and thus have a direct pecuniary interest in the result." And once more—"We may be permitted, without being very uncharitable, to surmise that the contingent effect upon shares, now at a discount of seventy-five per cent, may by possibility have some influence on the votes of honourable members." Subsequent allegations of *deception* and *imposture* are trifles to this! We shall leave the miserable man, who could think or express himself so, to the repro-

bation—not of his conscience, but of the profession. This being so, what is the scheme—the *quid pro quo*—of the Medical Gazette?—Monopoly afresh! “There exist in London numerous schools of medicine, in which some of the greatest men of the past age formerly taught, and which are now adorned by successors not unworthy of those whom they have followed.” (Is Dr. Macleod at St. George’s?) These schools in other places, emphatically called “*great schools*,” and which clearly indicate *the hospital schools*, should be the “*recognised*” schools or colleges of the “*One Great University*.” And so, no private lecturer, be his talents ever so great, or ever so well attested—be his private school ever so well attended—the unbribed consequence of his industry and talents—has any chance in the mart for teaching with this forestaller. But thoroughly to expose the drift of this new fangled system in favour of the hospitals, we must let our readers into a secret manœuvre of the last week. A meeting of *hospital lecturers* was convened and held,—we know not by what authority, we know not where, we cannot specify the day,—to petition against the grant of a medical charter to the University of London, of which there was not the slightest apprehension; and, one thing leading to another, the happy thought of petitioning for a monopoly to themselves occurred to some choice spirits; and one of the fraternity,—need we explain the rest?—threw out a feeler to grope the way for this dark deed.

Upon mature reflection, we repeat our firm adherence to the thoughts upon the constitution of the NEW Board for conferring medical degrees, which were submitted to our readers last week. The recognition of lecturers we touched on but slightly: it requires further development. No person should be recognised

as a lecturer till after some years’ professional practice: perhaps it may not be worth while to make an exception in favour of mere anatomy. The lecturer should undergo a strict additional examination in the medical subjects on which his certificate would be receivable, beside being required to prove his qualifications in such collateral branches of the physical sciences as may be requisite for the proper cultivation of his branch of the profession.

With this simple demand of a proper degree of knowledge, there should be no other restriction whatever on the teacher. At present, ill as the Apothecaries’ Hall is managed, its recognition of lecturers is conducted on sound principles.

It is most deplorable to reflect how little is done for the art of healing as a science in this country. A man, who rises to eminence in practice, owes his good fortune to a thousand accidents of manner and connexion, which much outweigh the value of professional skill; and when, at length, a young man of talent does succeed to acquire a decent competence by professional exertions, his time is frittered away by the distractions of practice, and he is unfitted for the labour of original research. It is somewhere remarked of the physicians cotemporary with Harvey, that no man above the age of forty admitted the truth of his splendid discovery. With all due respect for our enlightened seniors, we suspect the observation might be repeated if another Harvey were to appear. By making the situation of a lecturer the honourable consequence of recognised and distinguished professional knowledge attested by examination, the great body of students would have the best possible instruction; and young men would have another channel open to fame and independence than the accidents of good fortune. With the same view, prizes

of value for treatises or discoveries should be annually offered.

Some apprehend it would interfere with the current of private charity, to take from the subscribers to hospitals and dispensaries the election of medical officers. On the Continent, appointments to public charitable institutions, being in the gift of government, are bestowed upon the most worthy, after a public examination. It is not necessary to point out, what an impulse to exertions such situations, all of which are moderately paid, hold out to young students. We do not consider it impossible to establish a similar rule in our domestic charities; for the number of subscribers made by medical candidates for corrupt purposes, is but an occasional and scanty supply to the immense sums annually given to these establishments, and to the really charitable there can be but one object;—to elect the most deserving.

Whilst, however, hospital appointments are in their present condition, it is a reason the more for refusing hospital schools any monopoly in teaching.

ROYAL COLLEGE OF SURGEONS.

THE College of Surgeons has been lately the subject of a double attack;—first, that it purposes, as we announced a considerable time ago, to lay out a large sum of money, about five-and-twenty thousand pounds, in rebuilding its Museum and Library; and next, that it has acted with unreasonable severity, in rejecting some late applicants for its diploma,—and both charges are connected with the present investigation as to Medical Reform. The outlay of money will, it is conjectured, so much enlarge and strengthen the foundations of the College in Lincoln's-Inn Fields, that it will be difficult to remove them to the site of the New Faculty College that is to be: and it is presumed that

the present rigour of their examinations is a ruse to deceive the Committee. We have barely room for a word on both matters. The question is not now how the funds have been acquired: there is no charge of embezzlement against its members. But we are not lynx-eyed enough to discover a breach of trust in appropriating a portion of them,—even a large portion,—towards the building of a new Museum, or the enlarging of the Library; nor can we divine how this new Museum and Library will control the interference of the Committee and the legislature with the College of Surgeons. The Museum and Library will be equally serviceable under the new regime, and the situation is not a bad one.

If the motive of their supposed rigidity in examining at present be truly assigned, we detest the motive, and laugh at its folly; but if their examinations, in times past, were scandalously negligent, whereof there is no doubt, shall they even now, at the last moment, say, of their existence, persevere in their neglect of a sacred obligation, and pass unqualified persons, *because* such have passed hitherto? The truth is, that, like the building scheme, which was adopted a considerable time ago, we have reason to know the examinations of the College had become much stricter some time before a Parliamentary Committee was a matter of certainty.

EFFECTS OF TARTARISED ANTIMONY IN DILATING THE OS UTERI.

BY JOHN LANGLEY, ESQ., SURGEON.

AT three o'clock, P.M. of Friday the 21st ult., I was called to attend a young woman of plethoric habit and rigid fibre, 21 years of age, in labour with her first child. I was then informed she had been suffering severe pains during the day, which having increased in intensity and frequency, her attendants deemed it necessary to send for me. On visiting her,

I found she had pains of such unequivocal character, occurring every five or six minutes, that induced me to press an examination per vaginam, believing, from their nature, the labour must have progressed to an advanced stage; but, to my surprise, I found the os uteri with difficulty admitting my finger, extremely rigid and unyielding, the foetal head presenting, and pressing firmly upon it; the pelvis sufficiently capacious; the bowels had been frequently and freely evacuated; but she experienced a most distressing inclination to pass urine, without the power. Accompanying this state, there was a hard and frequent pulse, dry tongue, and hot skin. To relieve the insupportable suffering from obstructed micturition, with difficulty I drew off rather more than a pint of urine, which so far gave relief; still the apparent, and no doubt real, suffering of my patient was excessive, the pains assuming a more than ordinary violent character. I determined forthwith to bleed her freely, which proposition panic-struck her mother and self, both of whom positively and resolutely refused a compliance with my wishes, and in such a manner as rendered a perseverance unavailing, notwithstanding I described, in strong terms to both, the risk they incurred from such contumacious conduct. In the hope of inducing a relaxation of the contiguous parts, I threw into the rectum four injections of thin warm water gruel, at intervals of about an hour; still the same relentless rigidity of the os tincæ, and all the parts concerned in parturition. Reflecting upon the relaxation which supervenes upon the spontaneous vomiting which so frequently occurs, from sympathetic gastric irritation, during the last stage of uterine dilatation, I thought myself justified in anticipating, or rather imitating, nature in her operation, and decided upon giving small doses of tartarised antimony, which I did in quantities of one-sixth of a grain every twenty minutes in a little gruel, unconsciously to my patient. The second dose produced considerable nausea and gentle diaphoresis; and, upon again examining, I found the os uteri in a more favourable state. I gave a third and fourth dose, the latter of which excited vomiting, accompanied with profuse perspiration. From this moment an unusually rapid dilatation of the os uteri took place; the head descended upon the perinæum, and the external parts yielded most favourably to the passage

of the head, and my patient gave birth to a fine living child at nine o'clock.

I do not hesitate to affirm, from analogy in similar cases, that many hours of suffering and anxiety were saved to my patient, and which I alone attribute to the effect produced upon the muscular system by the administration of the antimonial.

French Hospital Reports.

HÔPITAL SAINT ANDRÉ DE BORDEAUX.

Affection of the Superior Portion of the Medulla Spinalis cured by Electricity.

— Girard, a cook by trade, had made many voyages, and had generally enjoyed good health. In two or three voyages he had been seized, without any known cause, with severe symptoms of paralysis of the upper limbs, which were cured by prompt antiphlogistic treatment—blisters and demulcent drinks. During the last voyage which he made to India, the same symptoms occurred and were combated by the like treatment, but without the same success. His general health, whilst under the care of M. Moulinie, Surgeon-in-Chief to the hospital, was good, the sensitive and locomotive powers of the upper limbs being only affected. There is a constant feeling of pricking and numbness in these parts, and motion can only be performed with great difficulty. General bleeding has been practised, and sixty leeches have been twice applied opposite the origin of the brachial plexus of nerves; purgatives, composed of aloes and jalap, have been given, and dry frictions; anodyne and stimulating fomentations have been used, but no treatment hitherto has arrested the paralysis. Recourse has therefore been had to the employment of electricity; one of the conductors of the electrometer of Lanne was placed on the upper part of the spine, and the other conductor alternately in either hand. This mode of treatment was had recourse to seven times during twenty-two days, and for the space of ten minutes each time; at the end of this period locomotion and sensation in the limb was completely established, and the patient has since returned to his employment.

The phenomena observed during each sitting could be divided into local and general. The first consisted in a nervous excitement of the upper limbs, so that the patient could use more force and could execute some few movements. This excitement gradually diminished after the first use of the electricity; the pricking sensation disappeared after the second exhibition, and the sensibility became more normal; the circulation was accelerated, and the skin, at first dry, became moist.

Italian Hospital Reports.

HÔPITAL MILITAIRE DE CALVI, CORSE.

Gun-shot Wound of the Arm — Amputation —Torsion of the Arteries.

A MAN was brought into this hospital, from the prison, with a gun-shot wound in the arm, which had been occasioned two days before whilst resisting the police. There was no hope of preserving the limb, for not only was the fracture comminuted, but gangrene had already commenced in the surrounding parts. M. Ferrus therefore proceeded to amputate the arm, but, to his dismay, on attempting to apply ligatures, found that they were not sufficiently strong to be tied. No others being at hand, torsion of the arteries was practised with a common pair of forceps, and, fortunately, was not succeeded by any hæmorrhage. The stump rapidly healed, and the patient is now confined in the prison at Toulon awaiting his trial.

British Hospital Reports.

ST. BARTHOLOMEW'S HOSPITAL.

Stricture of the Urethra—Calculus in Vesicæ.

An elderly man, upwards of seventy, was admitted with a stricture of the urethra, under which he has been labouring during the last two years. His existence during this time has been rendered very miserable, in consequence of his being compelled to void urine every hour with a catheter. Mr. Earle sounded the man, and felt two or three small stones in the bladder. Mr. Earle injected the bladder, and soon after there was a discharge of fluid from the rectum, which led him to believe that there was a fistulous opening between the rectum and urethra (an opinion which he has since abandoned). When the patient becomes more comfortable and easy, the operation of lithotomy will be performed.

(This is a case in which Mr. Earle thinks the high operation would be preferable to the lateral one.) The operation of lithotripsy could not be successfully performed in this case, as the patient would not be able to expel the particles of stone, the expulsive power of the bladder being considerably diminished.

CORRESPONDENTS.

SEVERAL communications have been lately received, which are so illegibly written, that no use can be made of them. We request our numerous friends to attend to this intimation.

Medicus.—There will be a radical reform in every branch of the profession.

A Lecturer.—We have alluded to the private meeting of certain lecturers without having those in London apprized of it, and their petition to the Privy Council against the London University. This hole and corner junta will find to their sorrow that the demise of their monopoly is at hand.

W. C.—We know the difficulty, but it may be overcome.

G. T. D.—Is it not worth treble the amount?

Justus—Gracchus—Fairplay.—There will be a power of granting degrees in London; but it will not be conferred on any medical school to the injury of the rest; or on the College of Physicians, even when it will be modernised. The examiners should be elected by ballot from the recognised lecturers in London, every six months, and the examinations held half yearly. A Reformed House of Commons will not sanction either an old or a new monopoly.

A Licentiate.—Our correspondent asks us, what improvements in science or therapeutics have been made by the College of Physicians and Apothecaries' Hall? We answer, not one.

M.R.C.S.—In what better manner can the College expend some of its funds than in enlarging its Museum and Library? No member can reasonably find fault with this. The Theatre does not afford room for half the members, and who will complain of its holding double the number it does at present?

A. T.—All the communications have been forwarded, as well as the French 4to of M. Double, to Mr. Warburton.

An Inquirer.—The Fothergillian gold medal, of the Medical Society of London, was awarded to Mr. Clement of Shrewsbury; and the silver medals to Dr. Negri of Poland-street, and Mr. Cole of Charlotte-street, Fitzroy-square.

Z.—We have received similar complaints against an Examiner at Apothecaries' Hall, who, it is said, which we do not believe, seems disposed to reject every one. We should like to know, however, whether he was ever examined himself, and recollects the feelings of a candidate, or whether he was in practice before August, 1815.

J. H. C.—Lugol's preparations as published in No. 108. The tincture of iodine is decomposed by water or bitter infusions.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXX., DELIVERED APRIL 2, 1833.

GENTLEMEN,—My next duty is to enter upon the surgical consideration of diseases and injuries of particular organs and regions of the body; with reference, however, only to cases which I have not had the opportunity of explaining in previous lectures. I will commence with *wounds and injuries of the head, and their consequences.*

The observations which I shall have to deliver upon this important subject, will relate

1st. *To superficial injuries, i. e. wounds and contusions of the scalp;*

2ndly. *To fractures of the skull;*

3rdly. *To wounds of the brain;*

4thly. *To compression of this organ;*

5thly. *To concussion of it;*

6thly. *To inflammation of the brain and its membranes from external violence.*

1st. *Superficial injuries.*—Gentlemen, no doubt all of you are aware that a free intercourse subsists between the vessels of the pericranium and those of the dura mater, through the medium of the diploe of the skull. Now, it is partly in consequence of this communication that inflammation of the parts on the outside of the cranium is apt to be propagated to the dura mater. Hence all surgeons agree in setting down injuries of the scalp, especially contusions and contused lacerated wounds of it, as more serious cases than similar injuries merely affecting the common integuments of other parts of the body. Indeed, it is a maxim in surgery, that no wound of the head is so trivial, as not to require the strictest attention.

The scalp is often the seat of erysipelas, which, in certain constitutions, will be brought on by a very slight cut or contusion; the

inflammation spreading rapidly, and soon involving not only the scalp, but the forehead, eyelids, and greater part of the face. Too often also, notwithstanding the most judicious treatment, delirium, succeeded by coma, comes on, and the case has a fatal termination.

I know of several instances, in which the removal of very small encysted tumours from the head led to the production of phlegmonous erysipelas in so violent a form, that the loss of life was the result.

Contusions of the head frequently give rise to an effusion of blood under the aponeurosis of the occipito-frontalis. The swelling is generally soft in the centre, and hard at its circumference; hence the feel of it may lead an inexperienced surgeon to suspect that the accident is a fracture of the skull, with depression of the bone.

But, gentlemen, some tumours, occasioned by extravasated blood, lie immediately under the scalp, and cover all the upper part of the head, raising up the scalp in a manner that creates an alarming degree of disfigurement. In general, however, these accumulations of blood under the scalp from blows on the head, subside very favourably under the use of a few brisk purgatives, and the application of lotions, containing a proportion of the muriate of ammonia, diluted acetic acid, and camphorated spirit in them.

But should inflammation and abscess not admit of being prevented, fomentations, poultices, free openings, and washing out all the matter and putrid blood with a syringe and tepid water, is the proper treatment.

When the scalp is wounded, or severely contused, the hair should always be cut off immediately; and, I may say that, in many cases, it is a matter of prudence to shave the whole scalp, not merely that the wound may be rightly and conveniently dressed, but that every part of the outside of the head may be seen and duly examined.

Hæmorrhage is, of course, to be stopped, and the wound freed from extraneous substances and clots of blood. These are rules which, as I have repeatedly told you, apply to wounds in general.

Frequently the *scalp*, is not merely wounded,

but lacerated, bruised, and more or less extensively separated from the subjacent parts. In many instances, not only is the scalp thus torn and detached, but a portion of the skull is completely denuded, the aponeurosis of the occipito-frontalis muscle and the pericranium being torn up together with the scalp.

Here all the raised portion, or flap, of the scalp, however torn and irregular it may be, should never be cut away, but be immediately replaced, and laid down upon the exposed portion of the cranium. The scalp, as I scarcely need remind you, gentlemen, is exceedingly vascular, and nature is more successful in repairing its injuries than circumstances might sometimes lead you to anticipate. At all events, the chance of its preservation and reunion should be taken; for, if you succeed, you materially lessen the risk of necrosis of one or both tables of the skull. You thus expedite the patient's cure, and obviate the deformity which would ensue, either from cutting the flap away, or leaving it more or less displaced from the parts with which it was naturally connected.

If slips of adhesive plaster and a bandage be not sufficient to maintain such flap in the proper position, you ought to avail yourselves of the assistance of the interrupted suture; but as few stitches as possible should be made, because they are a source of irritation, and, in this situation, very likely to promote the occurrence of erysipelas. For the same reason, when they have been employed, they should be cut and withdrawn at an early period, that is to say on the removal of the first dressings.

When erysipelas follows wounds of the head, it is to be treated according to the rules which I have delivered in a former lecture on this species of inflammation. Cold washes ought to be applied to the head, copious venesection practised, the free use of leeches not omitted, and the exhibition of calomel, James's powder, and saline aperient medicines, actively followed up in the early stages of the case. When abscesses seem likely to form under the tendon of the occipito-frontalis muscle, and to bring on sloughing of that aponeurosis, a free incision down to the bone should be made without delay. It is an observation, made by Dupuytren, that in phlegmonous erysipelas of the head the integuments hardly ever mortify, like the skin of the leg from the same disorder; and the reason which he ascribes for the difference is an anatomical fact, namely, that in the leg the integuments receive blood only by ramifications from the tibial and fibular arteries, which lie very deep, while the skin of the head has the occipital, temporal, and frontal arteries directly under it; consequently it is not so easily destroyed by the mischief produced under the aponeurosis of the occipito-frontalis muscle, as the skin of the leg is by similar mischief.

Gentlemen, when you begin to practise surgery, you will find that, in the treatment of

suppurating wounds of the scalp, one object will constantly require your vigilance; namely, that of preventing the matter from spreading widely in the cellular tissue under the scalp, or in that under the tendon of the occipito-frontalis muscle. You must, therefore, be careful to make with promptitude the free openings required for this purpose, and apply pressure, with the view of preventing fresh accumulations.

Frequently, when a portion of the scalp has been separated from the subjacent parts, and replaced, it will unite at every point; but in other instances, the union may not be general, and collections of matter may form in certain places. Here one principal indication is to procure a ready outlet for the matter; for if you neglect to do so, it will not only destroy whatever union may have taken place, but diffuse itself to a great extent, and lead to a vast increase of mischief and danger. The loose cellular tissue, connecting the tendon of the occipito-frontalis to the pericranium, may be the seat of extensive abscess, and that aponeurosis itself mortify; yet the scalp itself will not slough, for it is highly organised, and has a most abundant supply of blood from the temporal, occipital, and frontal arteries. It lives, therefore, and conceals the extent of disease situated under it. The reason of what I am now explaining, has been well accounted for by Baron Dupuytren, who, in relation to the comparative risk of the skin sloughing in erysipelas of the head, and that of the lower extremities, makes some highly interesting remarks, the tenor of which I have already mentioned.

Fractures of the Skull.—When the solution of continuity is very fine, it is termed a *capillary fissure*—specimens of which I now show you—when more open, it is a *fracture*. The broken portion of bone may either continue on a level with the rest of the cranium, or be beaten in, or, as we say in the language of surgery, depressed. A depressed fracture is illustrated in the specimens which I now pass round. The inner table, being more brittle than the outer one, is sometimes much more extensively broken than the latter; and occasionally the violence applied to the head will fracture the inner table, and actually cause a depression of it, though the outer table may not be at all broken.

The old writers on surgery expatiated a great deal on the various directions and shapes of fractures of the skull, and amused themselves with giving different names to them accordingly; but all this was of no practical use.

The most important distinctions are into *depressed* and *undepressed fractures*, *comminuted fractures*, and *fractures of the inner table alone*.

In young subjects we sometimes meet with *indentations* of the skull, without fracture, a circumstance referable to the softness and elasticity of the bones of the cranium in the early periods of life; and sometimes you will

most with cases in which the bones of the cranium are separated from one another at the sutures. The latter occurrence is not frequent.

Gentlemen, you should also understand that, when violence is applied to the skull, the fracture may not happen to the part which is immediately struck, but in some other situation, more or less remote from it; this kind of accident is termed a *counter fracture*, or, more commonly, a *counter fissure*, of which there are several examples on the table. Fractures of the base of the skull are produced in this way; but not always, for a blow on the occiput or temporal bone may cause a fracture extending to the base of the skull.

Gentlemen, it was formerly the custom to inquire of candidates for a surgical diploma the symptoms of a fracture of the skull; and, I have no doubt that, in the times to which allusion is now made, certain replies of the most erroneous kind were expected and given. Vertigo, paralysis, sometimes stupor and loss of sense, circumstances specified by writers and lecturers, about thirty years ago, as symptoms of fractured skull, really denote injury of the brain, and not a fracture of the skull.

The simple solution of continuity in the bone, were it not accompanied by other mischief, would not be attended with any particular circumstances denoting its existence; and, in fact, every experienced surgeon knows that many fractures of the skull are, on this account, completely overlooked—never discovered; and the patients get well without a single bad symptom.

A mere crack in one of the bones of the cranium, *abstractedly considered*, is no more likely to produce any serious complaints than a simple fissure in any other bone; and, if symptoms of consequence do frequently attend the accident, they proceed either from the bone being beaten inwards, so as to press upon the brain, or from the mischief done to the parts within the skull by the same force that broke the bone itself. The same violence which breaks the cranium, may occasion a concussion of the brain, an extravasation of blood in or upon it, or subsequent inflammation of that organ, and its usual consequences.

A fracture, *without depression*, then, is not in itself productive of any dangerous effects, or of any symptoms peculiar to it, or by which its existence may be known. Hence, if the scalp be free from wound, the accident is not likely to be detected at all; but the want of precise information on this matter, I should say, ought to be of no importance in practice, because the treatment should be regulated by other considerations. Thus, if the symptoms indicate concussion, or compression, of the brain, or a tendency to inflammation of this organ, you are to act accordingly, whether the bone be broken or not. You are led to adopt rigorous antiphlogistic treatment, or to examine the bone, with the view of making a perforation of it, by entirely different reasons

than the existence of a *simple undepressed fissure or fracture*. However, when the symptoms indicate pressure on the brain, and the part struck is denoted by a wound, or ecchymosis of the scalp, you are then called upon to make an incision, for the purpose of ascertaining whether any *fracture with depression* exists; and, if this should not be the case, such incision may still be useful, because, if the symptoms call for the trephine, the part that has been struck is generally the proper one for its application. It is hardly necessary for me to tell you, gentlemen, that it is the most likely situation for any effusion of blood, and for any splintering or depression of the inner table. However, when you trephine under these circumstances, in the expectation of finding blood extravasated under the part to which the violence has been directly applied, you sometimes learn that this is not the case, and that the pressure is neither produced by an effusion of blood on the dura mater in this situation, nor by any fracture and depression of the internal table. Blood, in fact, is frequently effused in or upon the brain, in situations more or less remote from the part of the head which received the blow.

You are not to suppose, then, that fractures *without depression* are not often accompanied by bad symptoms, but only that the mere injury of the bone itself is not the cause of them. The same violence which breaks the bone may cause a concussion of the brain, an extravasation of blood in or upon it, or a subsequent inflammation of its substance or its membranes. But, gentlemen, fractures *with depression* are a frequent cause of dangerous symptoms, because they are attended with compression of the brain. But, it is a curious fact, that the symptoms do not appear to be constantly in a ratio to the degree and extent of the depression of the bone. Sometimes fractures with a manifest and visible depression of the skull are quite unattended with any bad symptoms, or any of those effects known usually to arise from pressure on the brain. I was called, the summer before last, to a hackney coachman, a patient under the care of Mr. Hooper, of the London Road, in one of whose parietal bones a depression as large as a crown-piece had been occasioned; yet he had no urgent symptoms of pressure on the brain, and ultimately got well without an operation.

Gentlemen, you are not therefore to employ the trephine in every example of fracture with depression, but only in those cases which are made urgently dangerous by the existence of such pressure on the brain as this organ cannot quietly endure. I may gentlemen, lay it down as a rule in surgery, *that you should never trephine a patient unless he be actually labouring under coma, paralysis, and other symptoms of compression in an urgent and dangerous degree.*

Fractures of the base of the skull are cases of so perilous a nature, that they are gene-

rally regarded as inevitably fatal. Whether the opinion be true to this extent is not an easy point to determine, because we never know positively, while the patient lives, whether the fracture has been of this kind or not; and if he recover, we have no opportunity of ascertaining the point by examination. Fractures of the base of the skull are produced by the application of great violence to the lateral parts of the head, or to the vertex and base, through the spinal column. If a person fall from a great height, and the top of the head come to the ground, the skull is operated upon by two forces—the resistance of the ground and the pressure of the body upon the base of the cranium: the bones are seldom displaced to any extent; the dura mater is generally lacerated; its blood-vessels and sinuses wounded; and blood consequently effused at the base of the brain. Indeed, such has been the degree of violence, that you generally find blood effused, not merely in this situation, but in others. I have opened several persons who died with fracture of the base of the skull, and the mischief noticed within the head corresponded in every respect to what I have now described.

Bleeding from the nose, mouth, or ears, when attended with other circumstances evincing the receipt of a violent injury of the head, and much consequent disturbance of the functions of the brain, has been frequently insisted upon as denoting a fracture of the base of the skull. But while, in some instances, such bleeding happens from slight injuries, not at all affecting the cranium or its contents, other cases are met with where, on dissection, extensive fractures are found of the petrous portion of the temporal bone, and of the sphenoid and ethmoid bones, though no bleeding at all had occurred from the ears, nose, or mouth.

Treatment of fractures of the skull.—If the fracture be unattended with depression, or with symptoms of a dangerous degree of pressure, either from this cause or from extravasation of blood, you must direct your views to the prevention of another source of peril, namely, inflammation of the brain, which may perhaps sometimes be caused by the mechanical irritation of the inequalities of the fracture, but generally by the same violence which broke the bone itself. The latter, at all events, is the view which I take myself. When the broken bone is not depressed, you can scarcely venture to trephine on the supposition that the inflammation of the dura mater and brain, which often follows such an injury, is owing to the mechanical irritation of the irregularities of the fracture; and, if this should not be the cause of the inflammation, as I believe it seldom is, then the infliction of additional mechanical injury by the operation would be the least rational and advisable measure that could possibly be adopted. Here, I believe, it is far more prudent to be content with antiphlogistic treatment, such as cold washes to the head, venesection, arteriotomy, leeches, the free-exhibition of calomel with tartarised antimony,

saline purgative medicine, and only mere slops for sustenance. Nor should the antiphlogistic regimen be altogether discontinued till three or four weeks have elapsed; for the records of surgery prove, that a disposition to inflammation of the brain or its membranes lasts a considerable time after the application of external violence to the head; and such disorder has attacked and proved fatal to many, who, supposing all risk over, have returned, prematurely, to their usual mode of living.

A doctrine has, of late years, arisen, that fractures of the cranium, attended with a wound of the scalp directly over the injury of the bone, are accompanied by much greater danger than other fractures of the skull, uncombined with such a wound. In short, it is alleged, that there is the same difference in this respect as prevails between simple and compound fractures of the bones of the extremities. I cannot say that the observations, which I have had opportunities of making on this part of surgery, would have led me to adopt this opinion; but it is entertained by that highly respected surgeon, Sir Astley Cooper, whose views of every part of surgery have great experience for their foundation. The point is important, because the doctrine might deter us from examining the state of the skull by an incision, and applying the trephine, when the patient's safety, perhaps, depended very essentially upon such measures not being postponed. Surgeons who subscribe to this view of the subject will naturally be as much afraid of cutting down to a fracture of the cranium when there is no wound, as of cutting into a simple fracture of the leg, and making it compound. They will be inclined to avoid this proceeding, and of course to refrain from trephining, whenever the fracture is not accompanied by a wound; while, if the fracture happen to be already exposed by the accident, they would probably apply the trephine for precisely the same symptoms as they conceive would not justify it when no wound of the scalp exists. If I feel certain of anything in surgery, it is that *the decision for the operation of trephining should depend upon the symptoms of pressure on the brain being urgent, dangerous, and unequivocally manifested*; and, I believe, whether there be a wound of the scalp or not conjoined with a fracture of the skull, it is your duty under those circumstances always to examine the state of the bone, and not to let your conduct be at all influenced by any analogy, whether true or not, between these cases and simple and compound fractures of the limbs. If the doctrine be true, which I am by no means prepared to deny, it should certainly teach us not to use the knife without any real occasion for an inspection of the bone; yet it must not deter us from dividing the scalp, when such examination is urgently called for on the principles which I have already specified.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833-34.

LECTURE XII.

Pathology of Jaundice—Co-existence with a Flow of Bile—Case of Aneurism of the Hepatic Artery—Independent of Mechanical Obstruction—Colouring of the Various Parts—Effect on the Milk and Humours of the Eye—Yellow Vision—Icterus Infantum—Jaundice with Preservation of Health.

GENTLEMEN,—To-day we have to enter upon the consideration of a subject, the nature and extent of which claims for it a more than ordinary share of importance,—I allude to that form of disease which is termed jaundice. I have selected this disease for our present lecture, because I think we may look upon it as presenting a series of phenomena, which form a distinct link of connexion between affections of the liver and the digestive tube. In the first place, jaundice, and I wish to impress this upon your attention, is to be regarded as a symptom rather than a disease *sui generis*, and that it is a symptom which occurs in many diseases of a most essentially opposite pathological character. There is nothing, for instance, more different than disease accompanied by acute inflammatory action and disease without any inflammation at all; yet we may have perfect jaundice as a consequence of the one as well as the other. No diversity can be more complete than that which exists between the jaundice, arising from inflammation and organic lesion of the liver, and that which results from simple mechanical obstruction of the biliary ducts. It is, therefore, to be looked upon not as a disease but as a symptom, and we may define it by saying, that it is a state in which the solids and fluids of the body are tinged more or less deeply with bile. Generally speaking, this presence of bile in fluids and solids, where it should not be normally, is accompanied by the absence of that secretion in the place where it is naturally found, the digestive tube. Yet it is an interesting physiological fact, and one of practical importance also, that we may have plenty of bile in the stools, during an attack of jaundice, or *that we may have jaundice co-existing with even a copious flow of bile*. This is a strong proof in favour of the opinion, that some cases of jaundice have no connexion or dependence on the absorption of bile into the system, as, in the instances to which I have alluded, there is no mechanical retention of bile; the biliary ducts and gall-bladder are open, the bile passes freely into the intestines, and yet the whole body is jaundiced.

I have told you, that jaundice is a symptom which is produced by a variety of causes,—these I shall briefly enumerate. Without

entering into the ultimate mode of action of these causes, and their separate effects on the economy, it will be sufficient for my purpose to mention them individually. The first of these causes I take to be mechanical obstruction to the exit of the biliary secretion. Under such circumstances one of these two things is supposed to take place, either that the bile, which is poured into the biliary duct and gall-bladder, and cannot get into the duodenum, is re-absorbed, or, according to another opinion, that the innervation of the liver is injured; in other words, that the liver is paralysed and unable to perform its ordinary functions, and that consequently it does not separate the materials of bile from the blood. The latter opinion has been advanced by men of high authority in the medical world, but when we find, on dissection, (as is not unfrequently the case in jaundice,) the biliary ducts and gall-bladder distended with bile, we cannot infer a paralysis of the liver as the cause of the disease, we must attribute it to the re-absorption of bile. I have taken mechanical obstruction to the flow of bile as one of the causes of jaundice. Now, you will find this to depend, in the first place, upon the presence of gall stones in the biliary or common ducts. A biliary calculus is formed in one of these ducts, it excites violent irritation, spasmodic pain, and often (but not always) jaundice. At my next lecture I will show some specimens of this obstruction. In the second place, the biliary ducts may, from various causes, become obliterated; they may be closed by adhesion, as the consequence of inflammation, or they may be impervious as the result of congenital malformation. In some cases children have been born without biliary ducts, in others the ducts have terminated in a *cul de sac*. A third cause of jaundice by mechanical obstruction is, where the flow of bile has been prevented by the pressure of tumours on the biliary ducts. Of this one of the most familiar instances is disease of the head of the pancreas, or malignant disease of the pylorus or duodenum. I have, on a former occasion, alluded to a case of jaundice produced by aneurism of the hepatic artery, one of the rarest pathological circumstances on record, and one which has not been hitherto described. So rare is it that, at a late meeting of the Academie de Médecine, that eminent pathologist, Cruveilhier, stated that he had never seen a case of it. I was so fortunate as to meet with an instance of this uncommon form of disease, and will take an early opportunity of exhibiting the preparation of it to the class. You will see by it how an aneurism of the hepatic artery may cause a complete obstruction to the flow of bile, and I shall be able to show you, that not only the trunks, but also the minute ramifications of the biliary ducts, are enormously dilated and filled with retained bile, and that these dilatations are continued up to to the peritoneal surface of the liver, forming as it were so many aneurisms by di-

loration of the biliary ducts themselves. The last cause of jaundice from mechanical obstruction, is that which depends upon the accumulation of scybalous matter in the bowels, a thing frequently met with in old persons. Dr. Marsh alludes to this form of the disease in his admirable paper on jaundice in the Dublin Hospital Reports, and brings forward cases in which the jaundice disappeared rapidly under treatment calculated to remove accumulations of hard fecal matter from the intestines. So much for the varieties of jaundice which depend upon mechanical obstruction. Before I quit this part of the subject it will be necessary to allude to another form of the disease, which bears some analogy to those already mentioned, namely, the spasmodic jaundice. With respect to this variety there exists a great deal of doubt; some persons maintain that the ducts are muscular, and consequently liable to spasm like all other parts of the muscular system; others deny the existence of muscular fibres in the ducts; while a third party are of opinion, that the spasm resides in the duodenum, and that the contraction of its muscular fibres is the sole obstacle to the free passage of bile. It is of very little consequence which of these opinions we adopt; the fact is, that this is a form of the disease which we occasionally meet with in persons of an hysterical or hypochondriac habit, but what is its exact seat we cannot ascertain. The probability is, that it is spasm of the duodenum itself.

The next class of causes, giving rise to jaundice, are those which are connected with acute or chronic disease of the liver, as, for instance, the different varieties of hepatitis and the existence of morbid growths in the substance of the liver. Here, however, it must be recollected that the occurrence of hepatic disease in the acute or chronic form does not necessarily imply the existence of jaundice; in other words, there are some cases of disease of the liver in which bile is freely discharged into the digestive tube, others in which it is not, so that the non-secretion of bile and the consequent production of jaundice are to be looked upon as accidental complications. I have seen a case, in which there was enormous destruction of the liver from suppuration, where one of the lobes was almost entirely converted into a bag of purulent matter, and the other extensively diseased, yet the patient had not the slightest tinge of jaundice.

We are ignorant, therefore, of the cause which determines the production of jaundice in one case of hepatic disease, and not in another; the question remains to be decided by future investigations. All we know is this, that it may occur or be absent in every form of acute or chronic disease of the liver.

The third great source of this affection is disease of the mucous surface of the stomach and duodenum, the most important, because it is the most frequent cause of jaundice. We are indebted to the researches of modern patho-

logy for a correct notion of this form of the disease, and for the invaluable light thrown upon its treatment, which up to the time of Bronsais had been extremely confused and empirical. Inflammation of the upper part of the digestive tube is an extremely frequent cause of jaundice, and this result is, generally speaking, *independent of any mechanical obstruction of the gall bladder or biliary ducts*. This phenomenon may be explained by calling to mind the various examples of sympathetic irritation, and by recollecting, that disease in one situation frequently produces disease in another, or, in other words, that we have an irritation of the stomach and duodenum, in which the liver sympathetically partakes, and, as a consequence of this, the biliary secretion is arrested. In a former lecture I alluded to the strong sympathy which is known to exist between mucous membranes and the glands whose ducts open upon their surfaces. It is supposed by some that the irritation existing in the duodenum may be extended to the liver, producing paralysis of the functions of that organ and jaundice. It would appear also that the yellow fever of warm climates is only a variety of jaundice depending upon irritation of the gastro-intestinal surface. On this point the best pathologists seem to have made up their minds.

The last cause of jaundice seems to consist of the sympathetic action of the brain upon the liver, and this is an extremely curious circumstance. There are numerous cases on record of persons who have received an injury of the brain becoming jaundiced, and the same affection has been repeatedly known to supervene on powerful mental emotion. Thus we find that Murat, on learning that his queen had assumed the sovereign power at Naples in his absence, fell into a violent passion, and became almost immediately jaundiced. The close connexion which exists between the brain and the biliary system has been long known; it is unnecessary, therefore, that I should enter upon its consideration, for the purpose of accounting for an occurrence the nature of which must be obvious to all. You will, however, find that jaundice is in the majority of cases connected with disease of the gastro-intestinal surface, and that this is one of the most common causes of the sporadic jaundice of this country. I shall return to this subject on a future occasion when we enter upon the consideration of hysteria.

Before I enter upon a description of the separate forms of jaundice, it will not be amiss to premise a few general remarks. I told you at the commencement of my lecture, that we define jaundice by saying, it was that state in which the solids and fluids of the body were tinged more or less deeply with bile. Now, is this definition to be received without any exception? and does it embrace all the solids and all the fluids of the body? I have stated, that in some cases you will not be able to detect the slightest trace of bile in the stools.

This is, however, but an apparent exception ; it is perhaps because the bile is too small in quantity to be able to overcome the diluting power of the ingesta, or that the portion of it which finds its way into the digestive tube is too small to be appreciable by our senses under these circumstances. The rule of universal colouring in this disease will not, I believe, hold good, at least there are certain fluids and solids which are tinged only in a very slight degree ; but the majority of the textures and fluids have been observed to be more or less distinctly coloured. For instance, we find the jaundiced tint appearing in bone, cartilage, muscle, in the cellular membrane, in the central positions of the teeth, but not in their enamel. It is doubted whether the hair is coloured or not, but it is the opinion of many that it is, and a professional friend of mine has assured me that he has had unquestionable proofs of the colouring of the hair. The membranes of the brain are distinctly tinged. I have seen the arachnoid and pia mater decidedly coloured in a case of dreadful gastro-duodenitis, to which I shall call your attention on a future occasion. The substance of the brain, however, has not been found to partake in this universal discoloration. Frank, who is a good authority on this point, states that the substance of the brain is never coloured, though the membranes may, and most commonly are. In my experience of jaundice, I have found the membranes distinctly coloured, but never could see any tinge of yellowness in the *substance of the brain*. I have, however, observed that when a horizontal section of the brain had been made in such cases, the orifices of the divided vessels, which are denoted by bloody points in the healthy state, seemed to pour out a quantity of yellowish blood, but the substance of the brain appeared white and normal.

With respect to the state of the fluids, you will find the blood distinctly coloured ; the saliva also is yellow ; the urine is loaded with bile, it stains the linen, and chemical analysis shows that a large proportion of the biliary secretion is blended with it. The perspiration is also tinged with it ; and if you apply a blister you find the exuded serum bilious. If a person, labouring under phthisis or bronchitis, should happen to get an attack of jaundice, the pulmonary secretions will be often tinged with yellow. The mucous secretions from the vagina and uterus are also discoloured ; but it is an interesting and curious fact, that the milk during lactation seems to escape the general impregnation with bile, and is never tinged. This would appear to be a beautiful provision of nature to prevent the child from being injured. Frank, who witnessed two epidemics of jaundice, one at Mayence, in 1754, and another at Ghent, 1742, states that he has never seen the milk tinged with bile. Dr. Marsh, in his paper on jaundice, mentions that in the case of one

unfortunate female a yellow fluid was squeezed from the breasts after death ; but this cannot be considered as a proof of the existence of bile in the milk during life.

In jaundice the eye almost always presents a very distinct yellow tinge, and yet it is a curious and interesting fact, that the patients very seldom complain of yellow vision. Out of several thousand cases of jaundice, Frank only met with five in which this symptom was observed. The occasional occurrence, however, of yellow vision in jaundice, has excited a good deal of interest ; and Drs. Graves and Elliotson, who have turned their attention to this subject, have made some ingenious and valuable remarks on this singular phenomenon. Dr. Elliotson's opinion is, that where this symptom is complained of, the cornea is in a state of irritation or inflammation, and that under these circumstances its vessels, which in their physiological condition are too small to allow of the passage of coloured fluids, become dilated, so as to carry bilious blood across the field of vision, and thus cause all objects to wear a yellow hue. To support this opinion, he brings forward the case of a jaundiced patient, who had a considerable degree of inflammation in one eye but none at all in the other, and who saw objects yellow with the inflamed eye, but of their natural colour with that which was free from inflammation. This case is, indeed, as far as it goes, extremely interesting, but I think it does not prove the point in question, namely, that the cause of jaundiced vision is irritation of the cornea, for it is a fact, that even when the cornea is deeply tinged, yellow vision is not of constant occurrence, nor does it affect all persons alike. One person sees objects in their natural colours ; to another under the same circumstances every object appears to wear a yellow hue, and what is equally remarkable, this yellowness of vision is frequently intermittent ; it is present to-day and disappears to-morrow. These are extremely curious facts.

The object of Dr. Graves on this subject, in the Dublin Medical Journal, is to explain the cause of the absence of yellow vision in certain cases of jaundice. He believes that the humours of the eye frequently escape the jaundiced tinge, and suggests that this may be a beautiful provision of nature for the preservation of sight. From his own observations he states, that the aqueous and, perhaps, the vitreous, humours escape. But, it may be objected to this, that when all the fluids, the blood, saliva, serum, perspiration, &c., are impregnated with bile, how is it possible that the fluids of the eye should escape ?—Does it not seem very extraordinary ?—It does, certainly ; but that it is possible seems to be established by the following circumstances :—you are not to conclude because all the fluids which are found to exist in the blood are filled with bile, that the secretions, properly so called, which do not exist in the

blood, should be also tinged with bilious discoloration. This is the answer which Dr. Graves makes to this objection—I recollect two cases of malignant cancerous disease of the liver, which were some time ago in the Meath Hospital, and which presented symptoms of universal jaundice before death. In these cases we found fluids deeply impregnated with bile,—every thing, in fact, seemed bilious and discoloured; and yet, you will hardly credit me when I tell you, that, on opening the gall bladder, *it was found to contain a quantity of beautifully limpid fluid, perfectly transparent, and of a high refractive power.* Here, then, is a fact to prove that we may have intense general jaundice, and yet find in a sac, existing in a system so diseased, a quantity of fluid perfectly free from any bilious admixture, proving, at least, that it is possible that the humours of the eye may in a similar manner escape. Dr. Graves further remarks, that, even where the humours of the eye happen to become tinged, the alteration in the colour of objects may still escape the observation of the patient; because the change takes place gradually and insensibly. The patient does not think every thing he sees is yellow; he believes still that they are white, because the transition from one colour to the other has been so insensible as to escape his notice. This reasoning may, I think, apply to cases of yellow vision coming on gradually, but will not explain those in which it has been of sudden occurrence. The other cause which Dr. Graves adduces as tending to prevent a patient with a yellow cornea from seeing objects of the same colour is, the want of some standard of comparison to judge by. He has no means of comparing objects; and, though he sees this piece of paper, for instance, (yellow) he thinks it is white, because every standard he looks to, every other piece of paper he examines, presents the same tinge. Dr. Johnson states, that most of the jaundiced patients, whom he has interrogated, were sensible of the alteration in vision to a greater or less degree, and observes, that the power of appreciating varieties of colour is retained, though we look through a yellow medium not deeply dyed, though yellow, of course, is made to enter into this composition. You will see this observation in the *Med. Chir. Review* for October last.

I shall conclude this subject with an observation which suggests itself to me, and this is, that the alteration of colour and vision may arise from other causes than the mere jaundiced condition of the eye; and that it may (I believe this has not been taken notice of before) depend upon direct nervous influence. There are cases on record of patients labouring under typhus fever, who, without being in the slightest degree jaundiced, saw every thing yellow. There are also numerous instances of various colours, differing from the natural hues of the objects, being seen by patients in consequence of affections of the

nervous system; and hence it is extremely probable that many cases of yellow vision in jaundice may depend upon a functional lesion of the optic nerves. I have one fact to bring forward on this subject of great importance. In the case of jaundice from aneurism of the hepatic artery, the patient saw every thing intensely yellow, until a few days before death, when all yellow vision subsided, and he saw objects of their natural colour, though the jaundice continued, if possible, more intense than ever. In this case there was no inflammation of the eye. I do not think that Dr. Elliotson's observations apply to all cases of this phenomenon. All that he has said is, that where the cornea is in a state of inflammation, there is a greater probability that there will be yellow vision in the affected eye or eyes; and this can be easily accounted for by the increased size of the vessels which the inflammatory process brings on. We may, however, conclude, that in some cases the alteration of vision may be owing to a yellow state of the humours of the eye, that in some it is the result of inflammation, and that in some it may be fairly attributed to a lesion of innervation. I think that the latter statement is borne out by the facts that there is a want of constancy in the occurrence of this phenomenon, that it is often of a more or less intermittent character, being one day present and another day absent, and that it has been observed in cases where not the slightest symptom of jaundice existed. We must also bear in mind, that some of the most remarkable nervous symptoms commonly occur in jaundice, such as coma, &c.; and we may inquire how far the occurrence of yellow vision may be looked on as an indication of an excited state of the brain, and so lead us to measures calculated to remove impending danger.

Let us now return to the more immediate consideration of *jaundice*. One of the first diseases of children is the *icterus infantum*, or, as it has been termed by nurses, the *yellow gum*. Children, shortly after birth, without any known cause, become suddenly jaundiced, and this, after continuing for some days, goes off, frequently without any treatment. This form of jaundice appears to depend upon some particular irritation of the intestinal canal, which seems to result from the circumstance of the digestive system being called into active exertion for the first time, and receiving a new stimulus from the mother's milk. It is a curious fact, that this form of jaundice generally disappears spontaneously. Now, it is remarkable, in this as well as in other cases, (when we recollect the nature of jaundice, and that there exists in the fluids of the body an irritating substance like bile) that the effects of an admixture of the biliary secretion with those fluids should not be attended with more striking symptoms. In some instances we shall have intense jaundice without any particular effect upon the economy. There is some itching of skin, ardor urinae, a little de-

pression of spirits, and vertigo, which last for a few days and then disappear. Dr. Gregory mentions many cases of persons affected with jaundice who went about their ordinary business, and performed all the functions as if in a state of perfect health, eating, drinking, and sleeping in their usual manner. I have myself seen persons who laboured under this affection for more than a year, and yet had all that time their digestion good, their bowels regular, the flow of urine natural, and the circulatory, nervous, and respiratory systems apparently conformable to the standard of health. Dr. Blundell gives the cases of two children who lived for four months, apparently well fed and healthy; and, on opening their bodies, it was found that the biliary ducts terminated in a cul de sac, and that, consequently, not a drop of bile had been discharged into the intestines. Sir Everard Home gives a remarkable case of the total absence of the gall bladder, and no passage of bile into the intestines, occurring in connection with a perfect state of health. These are curious facts, and should be borne in memory. I remember two cases of protracted jaundice in the persons of two male servants, who were admitted into the Meath Hospital with symptoms of irritation in the upper part of the digestive tube. From this both recovered under an appropriate treatment, but the jaundice continued in one for eighteen, and in the other for sixteen, months. One of them, a stout, well-built, and fully developed man, came into the hospital some time afterwards in the apparent enjoyment of perfect health, except that he had still the jaundiced colour. He wished to be taken into the hospital to get cured of his jaundice, stating that, in consequence of the peculiarity of his appearance, he could not get a place anywhere, and was in a very distressed condition. From these facts it seems fair to conclude that the symptoms of other affections, occurring after jaundice, are owing to some other cause than the bilious state of the blood.

Gentlemen, I find that my time is nearly expired; I cannot, therefore, enter into the various causes of jaundice to-day; at our next meeting I hope I shall be able to conclude this subject, and then pass on to the consideration of hepatic disease.

CLINICAL LECTURES

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, &c. &c.

At the Westminster Hospital.

LECTURE XI.

History of Mr. Guthrie's Instrument for Dilatation.

In order to have a dilating and dilatable bulb, I applied to Mr. Weiss, who did not at

first see how it was to be done; but on my mentioning that I wanted something which could be enlarged like Ruspini's ball forceps, the application of this kind of mechanism struck him at once, and he soon made me some instruments which, although rude on the first essay (and these I have by me), soon became more efficient and polished in their appearance. They were composed of three blades, gradually separating by the action of a screw which turned in the handle. This same mechanism he soon after applied to a two-bladed instrument, and thus the forceps for removing a stone from the bladder made their appearance, and were first used with great effect, and were brought into notice by Sir Astley Cooper. I thought I had now obtained an instrument which could not fail of fulfilling all my expectations, and was only disappointed by finding it did too much. The opportunity of dilating was too tempting to be resisted, and the consequence was, that it produced irritation in so many cases, and did so much mischief, that I was forced to give it up, and I only now use it in some protracted cases in which I wish to dilate the neck of the bladder, and that not even of late, for the force with which the instrument acts cannot be readily estimated. When these blades act by a screw which turns in the handle at six or seven inches distance, they dilate, or are readily separated when there is no opposing force; but when there is any opposition, their separation is easily prevented, and the screw is turned more than would otherwise appear necessary before any effect is produced; if it is not turned sufficiently nothing is done; and if it is turned a little too much, mischief is the consequence, and that very easily; so that, although I might wish occasionally to use it, I soon found that I must give it up from prudential, or rather selfish pecuniary, motives.

At this same time I had under my care a little boy, who lived in St. Martin's Court, with a stone in his urethra, apparently too large to find its way along the passage to the orifice; and Mr. Weiss made for me another instrument of a different kind, which I now show you, for the purpose of catching and pulling it through. It is a model in miniature, or nearly so, of the percussor now used for breaking up a stone in the bladder by Baron Heurteloup; and with the adoption of the screw in the handle, and the teeth in the grasping part, it is nearly a model of Mr. Weiss's latest invention for crushing a stone in the bladder, without the alarm which the preparation by position, &c., and the shock of the blow, give rise to.

Foiled in having a steel dilating instrument, I was much pleased with the idea of one made of softer materials, proposed to me by Dr. Arnott, which was to be dilated by air or water. When he first showed it to me, it was merely a piece of bladder fastened on the end of a gum catheter, but which, on attempting to use, I found would not pass along the

urethra. The first improvement was the addition of a moveable piece of ivory, upon which one end of the bladder was tied, and which piece of bone fitted the end of a hollow gum elastic bougie, to which the other portion of bladder was carefully affixed. This ivory was soon changed to metal, and the bladder for the muscular coat of the gut of the cat, which is very strong and thin, and as this in one trial gave way, and the metal end was left in the urethra, the metal was now made to pass the whole length of the gum bougie, which was also changed for a metal tube. Thus far the improvements were made by me, and the instruments were used in my room, Dr. Arnott being present. He after this prosecuted his inquiries with his brother, Mr. Arnott, who in 1821 published his observations on the subject, without mentioning the share I had taken in the matter. It was not worth while noticing then, nor would it be now, if I were not giving the history of the different attempts I have made to improve this part of surgery, and that Mr. Ducamp, a French writer, published a work in 1825, describing this instrument, and laying claim to it as an invention of his own, but to which it does not appear to me that he had any right, except inasmuch as the instrument was unknown in France, but certainly not in England. As the gut became soft and yielded when wet, it became necessary to cover it with silk, or other unyielding materials, and again with a smooth substance. In prosecuting my experiments, I soon found that filling it with air was a very uncertain business, and used water instead, which answered much better. In one other case in which I used it, the bag slipped from the tube, and caused so much difficulty in withdrawing it, that my patient took alarm, and left me, and in some others the effect was so uncertain, that it did not give the satisfaction I could wish. I now rarely use an instrument of this kind, either from its often failing, or being so troublesome, and placing the surgeon so much in the hands of the instrument maker, unless he has time and ingenuity to make them himself. I cannot say, however, that I think it has had all the justice done to it which it merits.

On the Destruction of Strictures by Caustic.

It is not my intention to enter into the history of the different kinds of caustic which have been employed by our predecessors in surgery, or of the methods of using them; you will find them related at length both in French and English writers, to whom I refer you. I shall confine my remarks to the methods at present adopted.

The caustics now used are two, the *potassa fusa* and the *argentum nitratum*; the first has been almost entirely abandoned with respect to the urethra, and the other has fallen into unmerited obloquy and consequent disuse. You must not, from this remark, suppose that

I am going to advocate its restoration to practice, for I am going to do no such thing; it would not be prudent to do so, even if it were proper, for the prejudices of mankind have been so greatly and effectually excited upon this point, that they must be gradually allowed to subside; they will not admit of being taken by storm. Like most other prejudices they have some foundation in truth; and it was the *abuse* of the *argentum nitratum* and not the *use* of it which has given rise to them. When a surgeon of reputation cures a number of patients by a particular remedy or remedies, his professional character is gradually, nay, sometimes rapidly, augmented; more cases come under his observation, and many that are not susceptible of cure by the means he employs; he is nevertheless constrained, or nearly so, to use them; mischief ensues, alarm is excited; it soon spreads, is fomented by the adversaries of the plan, and a mode of practice, which is really successful in many cases, is often abandoned from prudential motives. I honestly confess I dare not say to a stranger, whatever his case may be, and however useful a few applications of the *argentum nitratum* might be, that I mean to use it. I dare not do so until after a few visits, and we become better acquainted, and have more confidence in each other, perhaps only after he sees that he does not make much progress. I should lose my patient if I did, who would go to another, and might be told it was the very worst thing in the world; an opinion he would not fail to repeat. Such is the prejudice against it among the younger men in London, that when a man says he has been cured by it, the remark is, how lucky you were to escape; I would not suffer any doctor to burn me for all the world. Nevertheless the *argentum nitratum* is a valuable remedy, when properly and carefully used in appropriate cases and not abused. It has been supposed, 1st, that the *argentum nitratum* takes off spasm and irritation; 2nd, that it can destroy a long and narrow stricture; 3rd, that it effects a permanent cure. The concurrent testimony of all writers establishes the first fact, and it is now almost the only object expected to be attained from its use. It is, however, capable of doing more when properly and carefully applied; and at some future period, when the prejudice which has arisen against its use shall have passed away, it will again take its place with other means, as a very effective remedy in certain cases of stricture. That it is capable of making a passage for itself, through a long, narrow, and impassable stricture, which has become hard, gristly, and irregular, through time and repeated attacks of inflammation, I do not admit, and the attempt to do it, under such circumstances, has been frequently followed by the occurrence of great inflammation, the formation of abscesses, of fistulous openings in the perineum, and between the urethra and the rectum, of inflammation and abscess of the

prostate and the bladder, and of profuse bleedings which, with all or many of the preceding train of symptoms gradually lead the unhappy sufferer to the grave. That the cure is more permanent than by other means may in some cases be the fact, but on the whole it is doubtful; and Sir E. Home, the great advocate for its use, in his later years and publications, admitted the necessity for the occasional passage of a bougie, in order to prevent a return of the complaint. According to his method, a bougie, the size or nearly so of the passage, was to be armed with caustic; and if one of this kind is used, it ought to be armed when the bougie is made, and not introduced afterwards, and the distance from the orifice to the stricture having been ascertained and marked upon it, the caustic bougie should be oiled or greased, which is the best mode when caustic is used. A bougie of the full size, or nearly so, of the urethra, is first to be passed down to the stricture to clear the passage, and after a minute or two withdrawn, when the caustic bougie is to be passed, and the end or point, in which the caustic lies, and is barely exposed, is pressed against the stricture for the space of a minute. The first effect is to coagulate the mucous secretion of the part, forming with it a whitish soft substance, which has often been mistaken for a slough; the second is by its stimulus to relieve and remove the irritation existing on the surface of the stricture, so that the person often feels much easier after a slight application, makes water in a fuller stream, and is greatly surprised to find that the desire he suffered from to pass it every hour or two has been materially relieved. Sometimes, however, the effect is the reverse, and particularly where the application has been more severe, or the irritation has been of a nature not to be relieved by it. The part becomes more painful, the desire to make water greater, whilst the passage of it is altogether obstructed, or it passes by drops with great suffering, until, by fomentations, opiates, &c. the increase of irritation and inflammation has subsided. It acts, therefore, sometimes like a two-edged tool, and this has been another reason for its disuse, but it partakes on this point only of the property, which all other remedies have of doing the same, and the fact inculcates the necessity for great care and gentleness in its use, whenever it is had recourse to. When the application is steadily continued to the surface of the stricture for a minute or more, its continued effect is that of a caustic, viz. the partial destruction of the part, which injured a dead surface, must be thrown off by the usual processes of inflammation and ulcerative absorption separating it from the living part behind. Where the stricture is slight and thin, or narrow, this will in general be effected without much inconvenience, but when it is thick and hard it will not often be done easily, but, on the contrary, the inflammation will

cause a greater thickening of the part, and the long train of evils I have alluded to already, if not prevented by proper means and a speedy abandonment of the practice. If, however, the operation should be fortunate enough to succeed, the separation of the slough in the diseased part is often marked by a paroxysm of fever, or the occurrence of an alarming hæmorrhage. The rigors with which the febrile paroxysm commences are strongly marked, and I am sorry to say take place occasionally even before the slough separates for the last time. They frequently occur after every application, or every one which has been in the least severe, and in such cases forbid its continuance. They are dependent on a particular sympathy which exists between the urethra and the system at large, and will occur as readily from violence as from the application of any caustic whatever. I know a medical man who had suffered from Walcheren fever, and who almost invariably had a paroxysm whenever caustic was applied, or a large bougie was used so as to cause irritation; and the first paroxysm was always followed by others at regular intervals, so as to reproduce his Walcheren ague, which was only cured by the administration of bark, &c., in the usual way. This sometimes takes place in a less marked manner; and whenever the return of an irritation or pain is periodical and regular, quinine will in general, in combination with bark and opium, be found the best remedy, when exhibited between the periods of illness.

The hæmorrhages from the urethra are caused by the sloughs separating and leaving the cells of the corpus spongiosum exposed, or by the ulcerative process extending to some small vessel, the canal of which is partially opened. These, it is said, cease of themselves, although not until a great loss of blood has been frequently sustained, and it has been recommended to let the parts alone. I cannot give you any opinion formed from personal experience, as I have never seen one of these bleedings from caustic; but I conceive that they should be met and treated like hæmorrhages from the same place from other causes, which appear to me to be of a similar nature.

The most alarming hæmorrhages I have met with have been from common causes; and I will mention to you two of them of the most prominent kind, as they also point out the practice to be pursued in such cases.

WESTMINSTER HOSPITAL.

THE governors of this hospital assembled on Thursday, the 6th inst., in considerable numbers for the purpose of electing Mr. B. Lynn, the assistant-surgeon of the hospital, fourth surgeon, on the retirement of Mr. Lynn, sen. Those only appeared to attend who took an interest in the proposition, which was carried

nearly unanimously, and Mr. B. Lynn was declared a surgeon of the hospital, and the notification of the vacancy in the office of assistant-surgeon was made to the weekly board, in order that the election of that officer might take place, in the manner prescribed by the rules of the hospital.

The only remarks which relate to professional subjects were made by Mr. Guthrie; and as we have reason to believe the governors will adopt some of them, and as we hope they may, we give them as shortly as possible. He said, he should vote on the present occasion for Mr. B. Lynn's being made a surgeon of the hospital, because he thought that when a man had attained nearly fifty years of age, it was quite time he should cease to have the title of assistant prefixed to his name; for, however desirable it might be for young men to bear it, there could be no doubt of its being a very odious one for men of mature age, and he hoped the governors would take the whole subject of the surgical appointments into their consideration, and make such alterations in them, on going into the new hospital, as would remove many evils which existed, and which were alike disadvantageous to the poor, and to the interests of surgical science. By the present mode, a surgeon, when once elected, remained in the office for life, and retained the office long after he was competent to the performance of its duties. It was quite useless to say that a man of eighty or ninety years of age was equal to the duties required of him. The public would not allow, the governors themselves would not permit, a surgeon of that age to operate on them, and he thought it only fair they should act towards the poor as they would be done by themselves, and it was impossible to prevent a man, holding the office of an operating surgeon, from doing operations, long after the period they ought in justice to the poor to cease to do them, and when the rich never thought of applying to them for that purpose. Another evil, was, that young men were kept out of situations they ought to fill, and would fill with greater advantage to the public; and they were kept out of them so long that they might almost be too old themselves to do the duty properly when they succeeded to them. He felt satisfied that the performance of operations, or of the other duties of a hospital, were of no personal use to a surgeon after sixty-five years of age; they neither added to his professional reputation, nor to the improvement of surgery; they only prevented young men from doing them, from improving themselves, from increasing their reputation, from having those opportunities which would enable them to advance the art and science of surgery. It was from the younger men, and those in the middle period of life, that improvement was to be sought. There were but few instances of men past seventy years of age doing anything personally for the advancement of surgery. He therefore hoped the governors would con-

sider the propriety of making an alteration in the surgical department on entering the new hospital. That they would set an example which he trusted other hospitals would follow, and the benefits to be derived from it, he was satisfied, would be greatly and highly in favour of the public. He thought they might make a rule that every surgeon, on completing his sixty-fifth year, should be appointed a consulting surgeon, whether he liked it or not, and earlier if he wished it, and the governors considered him deserving of that honour; for he did not hesitate to say, that it was a great honour to be considered worthy of the office of consulting surgeon to a London hospital, and one which at that age, if he ever lived to attain it, he should be very proud of enjoying. The result of this arrangement would be, that young men from thirty to thirty-five years of age would succeed to the office of surgeons, and not men of fifty. For his own part he should wish to see three consulting surgeons and three surgeons to a hospital, rather than three surgeons and three assistant surgeons. The duty would be much better done, and the poor more efficiently taken care of. The surgeons would then be young men capable of doing their duty, and ought to be made to do it or resign, and he would only allow of one assistant when there were not three consulting surgeons, but never when there were. His wish was to see young men, or men in the prime of life, or at least mature life, in the office of surgeons of hospitals, and old men, or even elderly men, in that of consultants. As to the emoluments derived from the office of surgeons, he believed that was the cause of the evil, but it might be easily rectified. They were of two kinds direct and indirect. In some of the large hospitals he understood the surgeons received 700*l.* a-year from the fees of the pupils. In the Westminster Hospital it did not now exceed 140*l.*, and these sums might easily be divided between the parties, giving to the consultants, who came once a week, one-third, and to the surgeons, who came every day, two-thirds. He was satisfied the young men would be content, and he thought the older ones ought to be; and that it would be more honourable to them than to hold an office for the sake of the emolument of it, long after the public had decided they were unfit for the performance of the duties of it as operating surgeons. As to the indirect emolument, it was often great, very great. The governors, when they elected a man surgeon to a hospital, conferred upon him the greatest favour they could bestow. They placed him in a situation in which if he had anything in him, he might show it and distinguish himself, and all that any man could ask, was to have that opportunity given to him.

There was another evil attending the present plan, which he must mention at the hazard of detaining them too long. When an assistant-surgeon was elected, he might be a man of good promise although young, but

when his turn came to be made a surgeon, he might by no means be well fitted for the office, nor be deserving of it; nevertheless the friendly feelings of the governors would give him the situation, solely because he had been an assistant-surgeon, and greatly to the disadvantage of the poor, about whom they professed themselves to be so much interested. If they had no assistant-surgeons, except when the number of consulting surgeons was deficient, they would have older men, and men of more character and knowledge, competing for the office of surgeon, and which they could not do for that of assistant, for the place of assistant was often made a very disagreeable one. He hoped, in conclusion, the governors would be pleased to take his observations into consideration, in drawing up their future regulations, and expressed his readiness, in the absence of his colleagues, to propose to them, if it was their pleasure he should do so, Mr. B. Lynn as a supernumerary or fourth surgeon to the hospital, but which appointment, he trusted, would not be drawn into a further precedent, inasmuch as there would not be duty enough for more than three surgeons in the new hospital, and that a greater division of it would be injurious to what was his greatest object, the improvement and advancement of surgery.

TRANSLATION OF M. ALIBERT ON
THE DISEASES OF THE SKIN.

BY SAMUEL PLUMBE, M.R.C.S.

*Late Senior Surgeon to the Royal Infirmary
for Children, &c.*

On the Etiology of Erythema.

Erythema assumes so many forms that it is desirable to class its causes very correctly. Sometimes it is apparently sporadic. The epidemic form is often attributed to atmospheric agents, to the nature of the aliment, and to exposure to heat; but these explanations are not always sufficient, inasmuch as the disease attacks frequently those who are both well fed and well protected from heat, or the reverse. New potatoes, as articles of food, have been occasionally blamed for the mischief; but we see as many cases occur in persons who have not used them. Beer and wine in like manner have been suspected, and they contain nothing pernicious.

The causes of endemic erythema, or the pellagra, we have been at much pains in investigating as far as limited means allowed. The patient, before mentioned as the subject of this disease, has given the following account of himself.—He was born in a French pro-

vince, and had arrived from Milan, having served only eight months in that neighbourhood. He had been accustomed from his youth to the labours of a peasant in his native country, his ordinary food being “*Bouillie de blé noir*.” After he became a soldier he never enjoyed good health, was melancholy and retired in his disposition,—he felt like an exile from his native country. He went to sleep in this state of health in a situation exposed to the sun; he awoke with severe headach, great redness, and tumefaction of the skin. The latter cracked, and in a few days exfoliated. The joints of the fingers and wrists exhibited deep cracks, and the skin generally was of a dark or copper-like hue; in this condition Assalini and Husson pronounced it a case of confirmed pellagra.

Persons of all ages, and of each sex, are liable to be attacked with this disease. Labourers in the field are most subject to it. They live in a miserable manner in damp close houses; many of them through the winter on the moist kind of bread, sleeping amidst their cattle. They have bad bread, and equally bad water. We may add, that their labours towards the end of winter are hard, and they are constantly exposed to great variations of temperature. To obtain a free use of their limbs, they throw off parts of their clothing, and often take their meals exposed to a mid-day sun in the fields. Enfeebled by these habits the skin loses its power of resisting, or rather recovering itself from, the effects of heat*.

The erythema paratime is easily known. It is most common among corpulent persons of either sex. M. Alibert, in this page, merely repeats what has been said before as to its known prevalence among such subjects, and infants who are not properly attended to.

The E. pernio, or chilblain, a half frozen state of the skin, is the most common cause of this form. It prevails most in marshy districts.

On the etiology of the E. *par adustion* there is of course little for our author to say. Persons

* A long list of authors on this disease are named by M. Alibert, some of whom we have ourselves consulted. Our countryman, Dr. Holland's account of it, which is to be found in the Transactions of the Medico-Chirurgical Society, is, we believe, the best extant translation.

exposed to heat by habit, such as smiths, resist its influence in an extraordinary degree. Of all animals man is most susceptible of the influence of caloric, undoubtedly from the prevalence of adipose matter in the composition of his diet, and his habits of drinking spirituous liquors. In the dissecting rooms it is constantly found that the cellular tissue of the bodies of drunkards burns with the greatest celerity. Spontaneous combustion in such subjects have taken place frequently to the astonishment of the spectators.

Treatment of Erythema.

There are cases of erythema which deserve serious attention; sedative applications are necessary, and they should be of a mild kind. If the stomach and digestive organs are out of order the first attention must be given to them. Lemonade, barley-water, butter-milk, chicken and frog-broth are to be depended on. If the disease arises from external causes, then bathing the parts with starch, or other mucilaginous solutions, should be had recourse to; these applications allay irritation of the surface. Poultices, or padding, soaked in a decoction of mallows, in milk, or in water, are also proper. When cases occur requiring attempts at resolution, ointment and lotions of lead are proper.

With respect to the epidemic erythema much quackery has shown itself. Each practitioner pursued his own hasty notions, and advocated them, but the examination post mortem disclosed nothing to support or oppose them. The disease was only fatal where the constitutional strength had been broken down by preceding diseases, as consumption, &c.

At St. Louis we found the emollient vapour baths very useful. The irritation of the skin was diminished by them, and when the skin became more quiet we employed aromatic fumigations and sulphur baths. Still, in general, we found gentle laxatives and general antiphlogistic measures the most successful. We have only to praise ourselves in our first trials.

The treatment of Pellagra consists of the exhibition of wholesome nourishing food. The meats of young animals, and broths of chicken or veal, milk, jelly, &c. In the case I have alluded to, the patient was starving, when he first arrived he was supplied with good food and recovered.

On intertrigo M. Alibert says that all greasy

applications are useless; vegetables, decoctions of a soothing nature applied, warm and weak solutions of starch, &c. are useful, and warm bathing is in every case advantageous, and he properly remarks, that sloughing of the nates is well understood every where.

The treatment of chilblains, says M. Alibert, is often the office of empirics, or they are treated blindly by the associates of the sufferer; spirituous solutions, or infusions, are applied, or styptic astringent infusions, such as those of gall nuts, &c. In northern climates friction with snow is a well known proceeding (a proper precaution if not a remedy).

The readers of this Journal will excuse us from touching further on this part of M. Alibert's subjects. The phenomena of burns are well understood here, the methods of treating them have been almost settled among English surgeons, and M. Alibert does not offer any addition to their knowledge.

The solutions of the chlorurets of soda and lime are spoken of as lotions in chilblains, and in cases of burns as being valuable agents; as regards chilblains their employment is backed by a recommendation of other measures in conjunction, which in effect are nothing but the means of giving warmth to the chilled part, but which probably are the most powerful agents in the cure.

Foreign Medicine.

Births and Deaths in Paris and the Departments, during the years 1831 and 1832.

In the year 1832 the births at Paris were—

	In Wedlock.	Illegitimately.	Total.
Boys	8853	4721	13,574
Girls	8273	4516	12,789
Total	17,126	9237	26,363

In 1831 there were 29530 births.

The number of illegitimate children acknowledged by the parents in 1832 was 2157, those abandoned 7080.

	Marriages.	Deaths.
1831	6654	25,996
1832	8219	44,463

Of the deaths during 1832, 18,602 perished from cholera, 386 from small pox. In 1831, 482 individuals died from the latter disease.

Referring to the bills of births, marriages, and deaths for the whole of France, we see that in 1831 there were 986,709 births,

246,480 marriages, and 802,761 deaths, which gives an augmentation in population to the amount of 183,948.

It results from the preceding tables that, during the 15 years from 1817 to 1831, the births in France were 7,490,951 boys, and 7,041,247 girls.

Inquiries have been made with the view of ascertaining whether the difference of climate in the different departments has any influence upon the predominance in the births of boys, but such does not appear to be the fact. It has, however, happened during the 15 years' that, 22 times, the annual births of girls has exceeded that of boys in some of the departments, to wit, once in Les Ardennes, twice in Le Cher, four times in La Corse, twice in Herault, once in l'Isère, twice in La Marne, once in La Rhone, twice in l'Yonne, once in Les Hautes Alpes, once in Les Bouches-du-Rhone, twice in La Haute Saône, once in La Dordogne, once in La Manche, and once in Les Pyrénées Orientales.—*Gazette des Hôpitaux*.

Phosphoric Acid in Croup.

BY A. BOYER.

Numerous are the remedies which have from time to time been extolled for their power in arresting diphtheritis, and numerous have been the failures in their employment. It is only in the advanced stage of the disease that this particular kind of inflammation takes place, and it is rare, at this period, that antiphlogistics, emetics, antispasmodics, &c., have not been tried and failed. Considering that the topical application of nitrate of silver to the mucus in the larynx, which has been lately recommended, causes prompt coagulation of the albumen, and thus gives rise to thickening, the writer has endeavoured to find out some remedy which shall produce all the beneficial results of this caustic, without participating in its injurious properties. From the experiments which he has made, he considers that phosphoric acid, prepared by nitric acid, possesses such desirable qualities. After investigating the nature of false membranes, which he concludes to be albumen or coagulated fibrine, he proceeds to examine the causes of the action of phosphoric acid upon these animal substances, and its modifications upon the organism.

1st. Put in contact with the mucous membranes, phosphoric acid produces an acute but brief degree of inflammation.

2nd. Injected into the trachea of a dog, it only appears to produce slight pain.

3rd. Its application to other living tissues determines acute sufferings.

4th. If the action is not prolonged, its degree of causticity, although energetic, only occasions superficial scars.

5th. Placed upon albumen or coagulated fibrine, it dissolves them completely.

Alkalies and acetic acids also enjoy this property, but in a slighter degree.

From the preceding experiments we may conclude, that if diphtheritis, nitrate of silver, and hydrochloric acid act by exciting a new kind of inflammation, which replaces, or at least modifies, the original kind, the same reasoning ought to apply to the phosphoric acid, since its action upon the tissues is, in this respect, precisely similar. It is, however, to be preferred to both these chemical agents, since it has been found to dissolve the false membranes; whilst, on the contrary, the nitrate of silver and hydrochloric acid augment their density. It is indispensable that this acid be entirely deprived of the nitric acid, which is used in its formation, since the latter partakes in the injurious properties of the two other remedies.

The author has made many experiments upon these different applications, and the result serves to warrant him in drawing the above conclusion.—[Want of space, however, forbids their insertion, although very interesting and conclusive.—Ed.]

Election to the vacant Chair in the Academy of Sciences, Paris.

M. Roux has been chosen member of the Academy of Sciences, vacant by the death of Boyer, on the 10th of February.

The number of voters was 55, of which there were 28 for M. Roux, 26 for M. Breschet, and 1 for M. Lisfranc.

Nomination of Surgeon to the Hôpital Cochin.

In consequence of the election of M. Guérbois to the Hôpital de la Charité, the situation of surgeon in the Hôpital Cochin becomes vacant. The candidates for the office are MM. Berard, jun., Manec, and Michou.

ON RUPTURE OF THE HEART.

BY JAMES DOUGLAS, A.M.,

Senior Physicians' Clerk to the Glasgow Royal Infirmary.

JAMES WALKER, æt. 67, clockmaker, was admitted into the Glasgow Royal Infirmary, Dec. 11th, 1833, under the care of Dr. Balmanno, by whose permission I report the case.

For some years past the right leg has been subject to swelling, and a month ago, after exposure to cold, both were severely affected.

At present his legs, thighs, scrotum, and anus are cedematous, and pit on pressure; breathing is difficult, but not more so in the horizontal posture; respiration is audible to bottom of chest, but is marked by subcrepitous râle; expectoration is mucous; action of heart is violent and irregular; impulse is stronger

than usual, and felt more widely, there being a distinct stroke above an inch to the left of the nipple, as well as in its usual situation; sounds are heard under the clavicles, and on the left side of the back, and have a flapping character; pulse 100, irregular; respiration 40; stools a little white; bowels regular; urine scanty and high coloured.

Diagnosis.—Great dilatation with hypertrophy of the heart; œdema of the lungs.

R. Olei ricini, 3vj.

— terebinth., 3ij. sumat statim.

Utatur misturâ scilliticâ in tussim.

App. vesicatorium sterno.

H. s. habeat T. opii ammoniat. 3j.

12th.—Rather more urine; four or five stools; but breathing seems more confined and oppressed; pulse 70, feeble and irregular.

R. Spirit. hordei, 3vj.

aquæ, lb. iss.

sacchari q. s. sumat in die.

Bowels became loose for some days, with alleviation of dyspnœa, and by the 19th, under the use of digitalis, urine had increased to four pounds. On the subsidence of the diarrhœa powders with squill were prescribed, but, on the morning of the 24th, he suddenly fell out of bed and expired.

Inspection, 25th.—On removing the sternum the pericardium was seen enormously distended with blood, and, when opened, about four pounds were removed, partly coagulated. The heart was found enormously dilated and hypertrophied, dilatation being predominant; and both ventricles were similarly affected. At the apex of the left ventricle a rupture appeared transverse, being a mere slit, three-eighths of an inch in length. On slitting up the ventricle, ulceration of the internal membrane, and of the muscular substance, was found to have taken place, rendering the part so thin that it had given way. Some shreds of fibrine were entwined among the columnæ carneæ around the ulcer.

A black spot was observed on the surface, about three-fourths of an inch from the rupture, which proved to be another spot attenuated by ulceration, communicating with the former, blackened by effused blood, and nearly ready to burst also. Some communication was thought to exist between the ventricles at this point, but was uncertain. Thickening of

the cardiac pericardium had taken place over the spots, doubtless for the purpose of preventing, if possible, the fatal catastrophe.

The interior of the aorta presented numerous atheromatous patches, and at the bifurcation the common iliacs were almost completely ossified, and scarcely a trace of internal membrane was left.

The lungs were œdematous.

Rupture of the heart is so extremely rare, though cases of it are to be found in pathological works, that Corvisart never saw an instance of it, and Laennec and Dr. Hope have each seen only one. I have, therefore, thought the preceding case worthy of being made public, more particularly as several of the cases, already pointed out, are very inaccurately described. My attention being directed to the subject I made enquiry about similar cases, and have heard of three, which occurred within the last few years in Glasgow. One of these occurred to Dr. Balmanno, in the person of a young lady at the Lunatic Asylum, who fell down dead while dancing in the airing ground. The rupture was in the *left* ventricle. He believes the specimen was not preserved.

In the possession of Dr. Mackenzie, the deservedly well known surgeon to our Eye Infirmary, I have seen a preparation, exhibiting a fissure, nearly an inch in length, and in the direction of the fibres, as if they had been merely separated about the *middle* of the *left* ventricle. The subject was an old man, between 50 and 60, who fell down and expired suddenly, while in the act of opening his own door. The substance of the heart when recent was soft and yellowish, but there is no ulceration. The pericardium was gorged with blood.

In the Anatomical Museum of the Andersonian Institution there is a preparation exactly resembling mine. The rupture is in the *same situation*, also transverse, and of much the same size, and produced by internal ulceration; there is also a second ulcer, not so far advanced: about sixteen ounces of blood were found in the pericardium. The patient fell off his chair and died instantly.

In the Hunterian Museum there is a section of the wall of the *right* ventricle, which is said in the catalogue to be from an old man, who married his maid, and died suddenly the

night after!!! It exhibits a rupture, about three-quarters of an inch in length, apparently transverse, and near the top of the ventricle; but the contiguous parts being removed the situation cannot be determined. Indeed, from the thickness, it is more like the left than the right. There is considerable ulceration inside.

To make any general remarks on the subject I shall not attempt, as enough may be found in the works of Corvisart, Laennec, Bertin, and Hope. I merely have thought it might be interesting to the profession to have a correct description of the cases of this uncommon lesion, which I have had an opportunity of accurately examining.

VESICAL MEDICATION.

On the Injection of Medicines into the Bladder.

BY MEDICUS.

THE urinary organs present an important feature in cholera morbus, and in a disease so desperate in its character, every resource that gives a chance of exciting the kidneys into action, and at the same time rousing the system, is unquestionably justifiable, and such appears to me to be the throwing of injections into the bladder. The powers of digestion belong to the stomach, but the urinary bladder may be rendered available for the purpose of conveying remedies towards the cure and relief of disease, and these remedies, properly prepared and administered through this viscus, will not interfere with the digestive powers, nor yet will their effects be eluded, as often takes place when the stomach is extremely irritable and torpid. I am of opinion that the paroxysm of ague may be prevented and the disease cured as effectually by medicines thrown into the bladder as by remedies taken by the mouth; and I am also well satisfied that the venereal disease in many of its stages may be also thus cured. The nervous influence issuing from the brain to the pulmonary and abdominal systems is very great; the nerves of the spine, the intercostal, the par vagum, the great sympathetic, the accessory, the diaphragmatic, all spread their paramount influence over their viscera, and in which the bladder, rectum, uterus, kidneys, and ureters, eminently participate, and therefore remedies applied through the bladder are unquestionably

in many cases of desperate disease worthy of a trial. The sympathy between the uterus and mammæ, as also the stomach, kidneys, bladder, spinal marrow and brain, is strikingly supported through the same system. The skin, the stomach, the rectum, the lungs, have all been rendered subservient to the purposes of conveying remedies to the system, but the bladder, so intimately sympathising with the stomach, and vice versâ, and so generally connected with the economy of life, has been strangely neglected; and I here repeat my opinion, so far as medicine is concerned, that its influence may be thus advantageously extended to the system; and I should hope that, should the cholera again appear, this channel for applying remedies will not be overlooked. It was thought by the late distinguished Dr. Darwin, from observing the immediate connexion between the stomach and bladder, that a retrograde action of the lymphatics took place, but I am of opinion that no retrograde action of the lymphatics arises, as the intercourse is carried on by a set of absorbents, the office of which is to maintain intercourse with the bladder, and thereby relieve each other in cases of disease or emergency. While on this subject I may observe, that during the reign of cholera morbus the use of Epsom salts was prescribed by a certain board, and by the various members emanating from it. Between the year 1830 and the present period, having been physician to a charitable institution, I believe that a quantity of this medicine equal to 5 cwt. was prescribed by me, and in no instance was there an individual who took this remedy, when cholera was very prevalent, who was seized with the disease, so that I am far from concurring in opinion with those who regard Epsom salts as predisposing to cholera morbus, but, on the contrary, I am strongly inclined to think it a preventive, and in this respect worthy the attention of the profession.

London, Feb. 4th, 1834.

Review.

The Dublin Journal of Medical and Chemical Science, including the latest Discoveries in Medicine, Surgery, Chemistry, and the Collateral Sciences. No. XIII. March.

This periodical continues to maintain its high position. The number before us contains nine

original communications, some of them of great practical interest. The articles are as follows:

- I. "On some Compounds formed by the Action of Chloride of Platinum and Chloride of Tin." By Mr. Kane.
- II. "Case of Urinary Calculi containing Human Teeth, removed from the Female Bladder." By G. W. O'Brien, M.D.
- III. "Medical Cases and Observations." By Mr. Riggs.
- IV. "Case in which a Foreign Body was supposed to be in the Trachea." By R. T. Evanson, M.D.
- V. "Two Cases of Popliteal Aneurism." By Mr. Collis.
- VI. "On Solidification of the Lungs in new-born Infants." By Dr. Joerg.
- VII. "Cases in which a Molar Tooth escaped into the Larynx after Extraction." By Dr. Houston.
- VIII. "On the occasional Occurrence of Mental Incoherence during Natural Labour." By W. F. Montgomery, M.D.
- IX. "Practical Observations on the Treatment of Diseases of the Lungs." By R. Little, M.D.

With respect to the calculi containing teeth as the nuclei, no rational conjecture could be formed of the manner in which the foreign bodies got into the bladder.

Mr. Riggs describes a singular effect produced by the ointment of tartarised antimony of a cartilaginous growth, about the size of a man's hand, on the Chest.

Dr. Evanson's case of a foreign body in the trachea is interesting. A child appeared to be on the point of suffocation. Mr. Crampton performed bronchotomy, but no foreign body was discovered. After a few days Mr. C. was expressing his astonishment to the parents, when the mother acknowledged she had removed a fish bone from the wound—it was that of a herring. Dr. Maunsel adds a case somewhat similar. A child was supposed to be labouring under croup; suffocation was threatened, brouchotomy performed, but death took place the day after the operation. On dissection, a herring bone was discovered in the ventricle of the larynx.

Mr. Collis relates the history of a case of double popliteal aneurism, for which he applied ligatures to both femoral arteries with success; and another case in which secondary hæmorrhage took place, and was restrained by pressure made with a newly modelled instrument, which is thus described:—

"The instrument which I made use of was one previously employed by Mr. Crampton, the surgeon-general, in a similar case, and

with good success. It consists of an iron hoop, about an inch and half in breadth, and sufficiently large to encompass the thigh; it opens behind, so as to admit of such dilatation as to suit a limb of any dimensions. This hoop has a slit in the anterior and internal part, into which is placed a moveable screw, with a pad attached. The pad is to be applied immediately over the compress, which has been put upon the artery, and then, by turning the screw, any degree of compression can be made upon the artery, whilst little or no pressure is made upon the other parts of the limb, and consequently no great obstruction, if any, is given to the collateral circulation. The hoop produced much inconvenience to this man, and was also the cause of inflammation, which terminated in abscess. This arose from the instrument being too narrow upon the part on which the limb rested, and I have now got one constructed with a broad flat surface; it is padded, and fits the under and outer part of the limb accurately, and on which the thigh rests without any inconvenience. To this are added two straps, one to surround the pelvis, and another the thigh, by which means the instrument is kept more firmly in its situation."

Dr. Joerg's account of Solidification of the Lungs, as the most frequent Cause of Death of New Born Infants, is deeply instructive. It is translated by Dr. West. The author observes, that the first inspirations, made by a new born infant, are, in consequence of the deficiency in its blood (a state resembling asphyxia by carbonic acid or other poisonous gases), naturally the most powerful, and at once expand the lungs so as to admit the rush of blood, so that the foramen ovale may close and become obliterated; in which case the infant respires regularly, oxygenizes the blood, and is able to cry and to drink. It is maintained that a difficult or too rapid delivery impedes respiration and induces organic disease in the lungs. The former, by compressing the brain (whether in the pelvis or by the forceps), weakens the infant to such a degree, that it respires imperfectly, and partially expands its lungs. The latter, too easy a labour, does not produce obstruction to the fetal circulation, which would render a wast of oxygen by respiration necessary. The consequence is that the infant only respires imperfectly, expands and fills its lungs with air

partially, and is never able subsequently to remedy this without the aid of art. In all autopsic examinations made by the author for several years past, a portion only of the lungs, from the greater half to an eighth or a tenth part, was found filled with air, and was of a red colour, while the remaining portion was impervious, and of a liver colour. When death occurred soon after birth, the condensed portion was susceptible of inflation; but if the fatal event occurred several weeks after nativity, it was found carnified, and incapable of being inflated. Sometimes the part between the healthy and diseased partitions was inflamed, or contained vomice; and the bronchi in some cases were inflamed and filled with mucus. In general the foramen ovale was open, and polypi were found in the heart and large vessels. The brain was often congested, or contained effusions and abscesses.

The author comments upon these facts in the following manner:—

"From these facts, and from observations made of late years during the progress of the disease, we are warranted in describing its nature and termination in the following manner:—The solidification, or continuation in the fatal condition of a greater or less portion of the lungs, so that during respiration their substance cannot be penetrated by the air. The blood, being still more incapable of penetrating, cannot be supplied with oxygen, and must consequently continue venous, and produce obstructions and dangerous congestions; while, at the same time, from its being unable to afford the stimulus requisite to the system for the continuation of its functions, an atonic senile condition obtains, attended with the utmost weakness, and complete atrophy, and terminating in death from hectic fever. The general morbid condition is, consequently, difficulty of respiration and impeded circulation, producing dangerous and even fatal congestions. Its terminations are,—1st, recovery; 2nd, secondary diseases; and, 3rd, death.

"I. *Recovery* ensues when the efforts of the infant to inspire are assisted by proper treatment, and the subsequent symptoms properly managed.

"H. *Secondary Diseases*:—(a) obstruction of the lungs, inasmuch as a portion of them remains condensed, which, without actually producing death, is very oppressive and dangerous; (b) chronic cyanosis, the foramen

ovale continuing open, and the infant being liable to constant suffering.

“III. *Death*:—(a) from apoplexy; in consequence of obstruction and congestion: (b) from suffocative catarrh, when the feeble respiration is not able to expel the mucus secreted in the bronchi, and the violent efforts at full inspiration produce bronchitis, and an over-abundant secretion of mucus, which the patient has not strength to get rid of: (c) from fever, the result of bronchitis: (d) from atrophy; the production of animal heat being prevented by the deficiency of oxygen, and the whole system paralysed by the want of its requisite stimulus.

“*Symptoms*.—When the infant comes into the world, the head is either found greatly swollen, (in which case abscesses often form in the part that has suffered from pressure, and inflammation or violent congestion of the brain ensues,) or else, though quite uninjured, and the delivery having been rapid and easy, it cries but feebly, breathes very short, and exerts the muscles of the thorax greatly; it is presently attacked with a faintness, and if it had been capable of drinking previously, now loses that power, the voice becomes hoarse and weak, and scarcely audible. Stertor and convulsions soon follow, the little patient becomes quite blue, the eye-balls turn, and the respiration remits, sometimes for so long as five minutes, till the scene at last closes with death. Should the illness continue for some days or weeks, a little short cough, the most certain sign of violent bronchitis, comes on; together with total weakness, atrophy, and hectic fever; and the child, at the very latest four or five weeks after birth, sinks under a violent attack of cyanosis, or bronchitis, or from the effects of the fever and atrophy.

“The best method of preventing the organic disease of the lung is, 1st, on no account to hasten the birth unnecessarily, because this never can be done without endangering the child; and 2nd, as far as possible to prevent too violent pressure on the head. The respiration of the new-born infant should be accurately observed, and the strength of its voice and manner of sucking attended to; and the moment we find the breathing too short, or the voice hoarse or feeble, and plaintive, or that the infant cannot suck properly, we must immediately exert ourselves to set

matters to rights. In the first place, the medical attendant should immediately endeavour to blow air into the lungs, till the thorax is properly expanded. The navel-string must not be cut too soon; the chest and back should be stimulated by friction with the hand or a brush; they might also be sprinkled with cold water and sulphuric ether, and the soles of the feet rubbed with a flesh brush. The child should be put in a warm bath, and the friction continued till it is able to cry loud and breathe properly, should these means not succeed, recourse must be had to internal remedies. An emetic consisting of a few grains of ipecacuanha, a drachm of oxymel of squills, or a quarter or third of a grain of emetic tartar, should be immediately exhibited. Afterwards a quarter, or, in urgent cases, half a grain of calomel should be given, for the purpose of producing general excitement by stimulating the intestinal canal, as well as of diminishing the too copious secretion of mucus in the bronchi, and diminishing the cerebral congestion. The repeated employment of warm baths, either simple, aromatic, (by the addition of thyme or majoram, and calamus aromaticus,) or restorative, (composed of milk or some mucilaginous fluid,) contributes greatly to revive the system, and restore and promote the circulation. Sinapisms of about an inch in diameter are occasionally to be applied to the chest or neck. The most unwearied attention is requisite to restore and maintain the health of the little patient. By the proper application of the above remedies, by avoiding all the *lædencia*, and even by delaying as much as possible every birth that appears to be proceeding too rapidly, a great many lives may be saved; still the disease is a dangerous one from the very first, and requires great care and watchfulness throughout.”

Dr. Houston's case, detailing the presence of a tooth in the bronchial tube, about one inch from its commencement, is deeply interesting. We are informed that after the tooth had been extracted it fell into the throat, and that difficult respiration had immediately succeeded. Several practitioners saw the patient, and differed as to the cause of his disease. Some could not believe that the tooth could have passed into the trachea; but dissection established the fact. It is surprising how a body larger than the rima glottidis could,

pass into the trachea. Mr. Key described a case somewhat similar, in which a sixpence was found in the right bronchus, and from this, and some experiments on the dead body, concludes that the right bronchial tube is the usual seat of foreign bodies which pass through the larynx.

The next paper is on Mental Incoherence during Natural Labour. By Professor Montgomery. The learned and experienced Professor narrates several cases of slight and transient mental disturbance while the foetal head stretches the os uteri in passing through it. These cases are extremely interesting; and, as far as our researches extend, have not been described by preceding writers.

The last article is on the Treatment of Diseases of the Lungs, &c., by Dr. Little. The author has tried oil of turpentine in the class of cases of which he treats as a rubefacient, and speaks of its effects in the highest terms. He has employed it in whooping-cough, asthma, croup, bronchitis, and pulmonary consumption, with the greatest advantage. He advises moderate friction with warm turpentine, and cautions us against exciting too much irritation. We fully assent to his opinion on the efficacy of this remedy, and have for six years preferred it in all cases to blisters. In deep-seated inflammations, it is in our opinion almost absurd to wait for the action of a blister, which allows the disease to advance, while the counter-irritation produced by turpentine is almost instantaneous.

We congratulate our Dublin contemporary on the valuable practical matter afforded in the number before us, and hope for a continuation of it.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, March 8th, 1834.

J. T. PETTIGREW, Esq., in the Chair.

Value of Auscultation—Pleuritis—Hydrothorax.

Mr. J. H. JOHNSON related with great minuteness a case of bronchitis followed by rheumatism. On percussion there was a dull sound over the inferior part of the left side, and egophony in the superior part of the chest. He concluded there were effusion and

consolidation of the lining membrane. The patient was now in an adjoining room, and might be examined by the Society. It would be found, that there was still absence of respiratory murmur in the lower part of the chest, and a dull sound on percussion. The diagnosis was difficult, as many causes might induce the dulness of sound, such as purulent infiltration, medullary sarcoma, and diffuse tubercle. He considered the prognosis unfavourable. After many other observations, the president requested Mr. Johnson to introduce the patient, which was done, and several of the members examined his chest. He withdrew after some time, and the discussion was resumed.

Mr. Costello complimented Mr. Johnson for the ability and judgment he had shown in the diagnosis and treatment of the case, and was happy that so strong a proof was given of the importance of auscultation. He made this observation, as a physician of some eminence had that day declared to a patient of his, that the stethoscope was nothing but quackery. He would relate a case to show that hepatisation might be extensive, and continue for several months though ultimate recovery might happen,—the case was his own, the particulars of which were, that some years since, while he was teaching anatomy in Paris, he wounded himself, was seized with encephalitis, hepatitis, pneumonia, and hepatisation of the lung, which continued for several weeks, and even for some time after his convalescence.

Dr. Somerville was gratified at the talent shown by Mr. Johnson in the case introduced by him, and felt proud that a surgeon was such an excellent stethoscopist. He wished to ask him, which cases of consolidation he considered most likely to terminate favourably?

Mr. Johnson replied, it was very difficult to answer that question.

Mr. Costello wished to inquire of any member of the Society, whether he had observed, that in dissections of children who had died of pneumonia after measles, the inflammation was in general confined to the lower margin of the lung, as he had witnessed many such examples in the hospital for children at Paris, the remainder of the lung being in a normal condition.

Dr. Johnson said, that the case of the patient which was first introduced this evening

might terminate by contraction of the chest, and that life might be prolonged for some time. In reply to a gentleman, who asked him to detail his treatment, he wished to observe, that the patient was his son's, but, were he prescribing, he would place most reliance on mercury, iodine, nitrate and acetate of potash.

Mr. Hunt, Mr. Greenwood, and other gentlemen addressed the meeting; and it was announced that on Saturday next, 15th inst., a draft of the petition on Medical Reform, recommended by the Society, would be laid upon the table.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Monday, March 10th, 1834.

W. KINGDON, Esq., President, in the Chair.

Cupping and Calomel in the Bronchitis and Peripneumonia of Children.

Previous to entering on the business of the evening, the President stated to the Society that, at the anniversary on Saturday last, medals were adjudged to Mr. Clement, of Shrewsbury, to Dr. Negri, and to Mr. Colé. That the subject for the Fothergillian medal for March, 1835, was "On the Pathology, Causes, and Treatment of Puerperal Fever." For March, 1836, "Diseases of the Larynx and Trachea."

Dr. Burne said, in reference to the late discussion on pulmonary diseases in children, that the red hepatisation was exceedingly rare, if ever seen, in pneumonia, but that the grey kind might occasionally occur; the most common inflammatory affection in children was bronchitis, for frequently when the substance of the lung was apparently affected the inflammation in reality did not extend beyond the bronchial tube; in such cases he had found the abstraction of blood by means of cupping glasses very useful. The loss of from two to six drachms of blood, taken by these means, had proved much more beneficial than the application of leeches, and generally succeeded very rapidly in relieving the congested state of the head and chest; when such relief was not obtained, mercury and emetics would not prove of much service. He had for some time constantly made use of this practice in a great number of cases, and

from what he had witnessed, did not think that the tender age of the patient was any objection to its use. Amongst other cases, which the Doctor mentioned, was a very severe one, in which the cupping glasses were applied in the evening, and were followed in the course of a few hours with decided mitigation of the symptoms. Ordinary medicines were certainly given, but he considered that the benefit derived was entirely attributable to the loss of blood.

Dr. Whiting thought that it was almost impossible to draw the line of distinction between peripneumonia and bronchitis; it was not to be expected, that that degree of hepatisation, which was found in adults, should be discovered in the bodies of children who died of inflammation, as this morbid appearance existed in cases which were of a chronic character.

Dr. Ryan agreed with Dr. Burne upon the unfrequency of pneumonia in children, but he could not coincide in his views as to the propriety of preferring cupping to the use of leeches; the irritation from the method, recommended by the Doctor, would be likely to occasion convulsions, since they had been known to occur from even the application of one leech. At one time he very much doubted the utility of applying a leech or two in bronchitis of children, but repeated experience had convinced him of the efficacy of the practice. When he looked at the sensibility of young infants, and how readily any source of irritation induced convulsions and death, he thought that cupping indiscriminately might prove a very dangerous practice.

Mr. Dendy felt gratified that Dr. Burne had confirmed his observations on the species of hepatisation generally found in the diseases under consideration; he could not, however, coincide in the opinion that bronchitis was so much more common than pneumonia, as the stethoscopic signs were not in general those which indicated the former; he thought that the objections of Dr. Ryan referred rather to the abuse than to the use of bleeding, for although it was necessary to be guarded in the application of leeches, he could not think that it was from the irritation caused by them or by cupping, that convulsions were occasioned.

Dr. Ryan said that Mr. Dendy had mistaken his observations, which referred to the comparative merits of leeching and cupping

children when labouring under bronchitis. It appeared to him that we should consider the effects on a hundred infants, and not in a case or two. For his own part, he should certainly hesitate to employ cupping in cases of very young infants or children, as he had generally found leeching, followed by other remedies, generally effectual.

Dr. Williams confirmed the practice of abstracting blood in pneumonic disease; he had pursued this practice boldly, although not extravagantly, for upwards of twenty-six years, and had felt satisfied with the result.

Mr. Headland considered that he was indebted to Dr. Whiting for the promulgation of his views on the use of calomel, for, since pursuing this treatment, he (Mr. Headland) had been more successful in treating these cases; he did not think that the stethoscope was so valuable as some members seemed to consider, for the sounds elicited by it were not generally necessary to discover the disease; in reference to cupping, he stated that its use in young children was not of recent date, for he had some years since witnessed it made use of to a great extent; bleeding, however, was sometimes carried to too great an extent, for occasionally a directly opposite treatment was necessary; he had once attended a case which was considered one of acute pneumonia, but which had proceeded to such an extent, that the further application of leeches must have terminated fatally. Dr. Gooch prescribed aromatic ammonia, and succeeded in rescuing the child from death. These cases, which were apparently affections of the chest, frequently depended on disease of the brain, and he conceived that it was in such cases that calomel was so valuable a medicine.

Dr. Blick considered that it was in such cases, where inflammation of the brain existed, that bleeding was imperious.

Mr. Roberts related a case where the administration of calomel in large doses in a child, had been followed by profuse salivation. He had found the vinum colchici exceedingly useful, frequently by its use succeeding in giving much relief, especially where the breathing was very loud.

Mr. Howell had witnessed great injury ensue from the use of large quantities of calomel in children. He agreed with Dr. Whiting in his plan of treatment, but did not think it necessary to use it to so large an extent.

Dr. Uwins thought that the inflammatory condition which affected the bronchial tubes had more reference to the state of the nervous system than practitioners generally recognised. He had noticed that one of the rabbits in which Dr. W. Philip had divided the eighth pair of nerves died in a state which would be considered as bronchitis. The physiology of Sir C. Bell on the nerves of respiration was too much overlooked. A child had been brought to him labouring under pulmonary inflammation, occasioned by a blow at the back part of the brain, at the part where it is supposed the respiratory nerves take their origin. Recollecting the origin of the inflammation he confined his treatment to the application of a blister over the ligamentum nuchæ, and the use of simple medicines, and succeeded in curing the child.

Dr. Whiting had met with a case of a similar nature to the one related by Dr. Uwins. There was present more of the symptoms of pulmonary inflammation, and, in addition, there was exquisite pain at the nape of the neck. The sounds, on auscultation, did not corroborate the other symptoms of inflammation. Leeches were applied to the neck, and succeeded not only in relieving the pain in that part, but also in dispersing the pulmonic symptoms. He begged to differ entirely from Mr. Headland in regard to auscultation, as he considered this mode of distinguishing disease highly important. He had never stated that calomel entirely did away with the necessity for bleeding: but that more deaths occurred from peripneumony where calomel was not prescribed was undeniable, and where this medicine was used the children seldom perished. The sloughing mentioned by Mr. Roberts and Mr. Howell was not, in his opinion, caused by mercury, nor were they cases of ptyalism, but were instances of the disease mentioned by Celsus and others, called *gangrena oris*.

Adjourned.

MEDICO-BOTANICAL SOCIETY OF LONDON.

Tuesday, March 11th, 1834.

Dr. RYAN in the Chair.

Chemical Constituents in Tea—Extract of Cubebs in Gonorrhœa.

Dr. SIGMOND read a paper by Mr. Judd, on the efficacy of the extract of cubebs in gonorrhœa.

rhusa, illustrated by several cases. The dose was from five to twenty grains, in pills, three times a day.

Mr. Everitt then delivered a lecture on the ultimate and proximate constituents of the different kinds of tea, which he illustrated by numerous experiments.

The Chairman then announced a vacancy in the office of Professor of Toxicology, by the resignation of Dr. Clendinning.

Dr. James Cadett was elected honorary secretary, in the place of Dr. Clendinning, who had resigned.

Dr. Sigmond announced that a paper on the extract of cubebs would be read at the next meeting, which would be held on the 8th of April next.

PROGRESS OF MEDICAL REFORM—
EDUCATION.

It is generally understood that the Committee will not suffer the evidence of the witnesses examined before them to be published pending the investigation. This is the usual course with select committees, and very proper too where the investigation may affect, as in the present case, the character and honour of any man. Having, however, no option in the matter, we are content to submit with a good grace to the resolution of the Committee, nor do we ask any credit for not exposing ourselves to be called to the bar of the House for an infringement of its rules. We leave the *merit* of acquiescence to one of our cotermporaries.

Without violating any order, however, we may inform our readers that the *virâ voce* examination has not yet commenced: it is understood that the work will begin in right earnest in the course of the next week; and, meanwhile, a mass of charters, by-laws, and so forth, has been collected, comprehending the whole *lex scripta* of the profession.

Though our lips must be sealed as to the particular evidence to be tendered to the Committee, we cannot see in what manner we are precluded by its operations from canvassing at the present time the state of the profession, or the nature of the remedies which seem to be indicated; nor does it argue in us the slightest disrespect to that body, or distrust in the impartiality of its investigation, or in the soundness of its judgment, that we persevere in criticising the defects and abuses of medical education and practice, with a view to their amendment. The Committee has yet to receive the opinions of practical men, to whom we should be happy to suggest a train of thought upon the subjects likely to be inquired into, whatever they may think of our conclusions. Whilst the violence of some in uprooting or upholding plainly indicates their respective objects—whilst one is incensed at the addition of a brick to the structure at Lincoln's-Inn-Fields, because of the increased labour of demolition; and another shudders at the possible desecration of the temple at Pall Mall East—we propose to ourselves the humbler task of examining our medical institutions, and, by contrasting them with each other, of pointing out their failings or merits, without arrogating to ourselves that all who differ from us are dolts or knaves. No time can be more proper for an impartial investigation than this important crisis. There is, undoubtedly, much information to be acquired by the Committee, which is out of the reach of any private individual; but much is also known, and there are many principles of medical education, of which the universal adoption may be reasonably contended for, although the full amount of corporation iniquity may not have been ascertained.

In our last number we published a,

document, by which our readers will be enabled to contrast the education required of a Licentiate in Surgery in the Colleges of London and Dublin. A good deal has been said latterly of the new-born severity of the College of Lincoln's-Inn Fields. We have already stated our opinion that the College has been for some time touched with compunction at the disgraceful nature of its examinations, as compared with those of Dublin and Edinburgh. We acquit it, therefore, of the charge of sacrificing a young man of competent knowledge, for the sinister motive of recommending itself to the Committee: and if a person, who might have passed under the lax system of two years ago, is now *bonâ fide* rejected, he cannot complain that the College adheres in his case to its general rule, in not admitting him to further examination till six months have elapsed.

Taking, however, the severest form of its examination, or rather comparing the general course of education it requires with the by-laws upon education of the College of Surgeons in Ireland, we cannot but be struck with the vast disparity in the means of obtaining the same professional rank in the two parts of the same kingdom. The reason of this difference is very apparent. Both Colleges possess no other legal rights than those a Royal Charter can bestow:—so far they are on equal terms. But, by Act of Parliament, no surgeon can be attached to a county infirmary in Ireland, unless he is a Member of the College. These appointments are numerous all over the country, and respectably paid. There are, in that country, no instances of parish paupers hired out to be drugged at eight pounds a-year! The English College has no exclusive legal rights. The Irish College, by reason of its privileges, is enabled therefore to exact a stricter education than can be required

at London, where candidates must be bribed to resort. There is another striking distinction in favour of the Sister Island, in that there is no competition between its College of Surgeons and its Apothecaries' Hall. The apothecary is not there presumed to be educated for general practice. Besides a knowledge of pharmacy little more is required of him than the simplest elements of medicine and surgery. On the contrary, in this country, the Company of the Apothecaries has alone the power of conferring legal rights, and, under this advantage, it requires of the mere apothecary a course of education as extensive as is exacted at Lincoln's-Inn Fields. From this rivalry between the two latter bodies, it is impossible for the College of Surgeons to improve its examination without risking a sensible loss of members, from the superior facilities offered by its powerful rival. These remarks, while they explain the degraded condition of our College of Surgeons in comparison with that in Ireland, manifestly point out the efficient remedy for the evil.

But omitting, for the present, any further comparison as to the nature of their governments, and of their examining bodies, (a most important particular this latter,) we are led to add, to what we have already written upon education in former articles, some remarks upon the mode of examination adopted in Dublin; and, in our opinion, worthy of universal adoption. The course of study—comprehending a perfect education in physic and surgery—embraces a period of five years. Before its commencement the student has received the average education of the schools in Ireland. This education is wholly classical; we confess we would wish to see the elements of the mechanical sciences have some place in the course.

It is not, however, to these points of

time and extent of study that we now allude. The great feature of improvement in the Dublin system remains still to be stated; it is this:—The course of study is divided into four sections; and in each of these must the student pass in classes a public examination, before he is allowed to be examined for his licence.

By this means the student's exertions during his noviciate are directed in the natural order of his studies, and his industry is kindled by the stimulus of public examinations; during which he is, in fact, not merely qualifying for the final adjudication of his right to practise, but also acquiring the public reputation of a promising and distinguished candidate for the honours of his profession. It secures, moreover, a thorough investigation in the whole course of the student's knowledge, and excludes the chance of an ignorant person passing, or one qualified being rejected. This admirable system in some respects resembles the manner of conferring degrees on the Continent, where a system of double examinations, first in the science, and subsequently in the practice of the healing art, is required.

To these comments, we have only time to add, that a complete knowledge of midwifery is exacted.

French Hospital Reports.

HÔTEL DIEU.

Wounds of the Radial Artery cured by Compression.

On the 26th of July, 1833, a fishwoman, æt. 40, presented herself at the hospital with an extensive wound, caused by the slipping of a knife, and situated in the first metacarpal space. There had been much hæmorrhage, which had reduced her to a state of great weakness. Pressure upon the radial artery arrested the flow of blood for a few moments,

but in a short time the bleeding returned, and could afterwards only be completely stopped by applying pressure to both the arterial vessels in the fore-arm. In consequence of the direction and situation of the wound, which was very deep, M. Grisolle did not think that a ligature could be placed upon the two bleeding orifices of the vessel without great difficulty, he therefore rolled some pieces of plaister into two solid cones, the apices of which, being placed upon the radial and ulnar arteries near the wrists, were there retained by means of one or two circular straps of plaister, and one or two turns of a bandage; the interval between the two cones allowed the blood to pass freely through the veins, whilst the circulation through the two great arteries was completely arrested. This mode of treatment did not cause either pain or numbness, the hand preserved its temperature, and at the end of fifteen days the compresses were removed, as the wound was perfectly cicatrised.

HÔPITAL DE LA CHARITÉ.

Colica Pictonum cured by the use of Croton Tiglium, Purgative Enemata, and Opium.

Humbert Sebastien, æt. 30 was admitted into the ward St. Michael, No. 7, on the 20th of January, with all the symptoms of painters' colic, which had been increasing in severity since the 17th, on which day he was first attacked. This patient, who is employed in a white lead manufactory, was in the hospital in August, 1833, for a similar attack, which yielded to the treatment with croton oil, enemata, &c.

21st. The colic pains are spread over the whole abdomen, but are most acute near the umbilical region; when the hand is lightly placed on the parts the pain is augmented, but if a considerable degree of force be used relief is given. The pains occur in paroxysms, and travel along the spermatic cord to the testicle, which appears retracted. The patient has vomited twice, and the matter is green, and of a very bitter taste. The tongue is white, and the digestive organs are much deranged, and there is a feeling of fulness in the throat. In addition to the preceding symptoms, the man complains of very acute pain in the head, which is more particularly felt in the frontal and parietal regions, and

which generally comes on immediately after each paroxysm of the colic. M. Rayer prescribed two drops of the oil of the croton tiglium, a purgative lavement, and a draught, containing a grain of the extract of opium. The first dose of the oil was followed in the course of three hours by three copious stools, attended by violent pain.

23rd. The pains have now almost entirely disappeared, the pulse has risen to sixty, and the patient has slept three or four hours; the bowels have been opened seven or eight times since yesterday. Ordered barley water, linseed enemata, and emollient cataplasms upon the abdomen.

24th. Humbert is now almost entirely recovered; the pains are gone, and his appetite and powers of digestion have returned. He left the hospital on the 27th quite recovered.

Chorea principally affecting the left side of the Body, cured by Blood-letting and Sulphur Baths.

Rosalie Rouillard, æt. 17, came into ward St. Joseph on the 2nd of January, attacked with chorea.

In the month of last July, she received a violent blow in the right hypochondrium, which was followed for some time by difficulty of respiration and delirium. Towards the end of the month of August she was, however, perfectly cured. Shortly after this time she complained of violent pain situated in the supra orbital region on the left side of the head. This pain, which disappeared at the end of some days, was followed by involuntary contractions in the muscles of the left arm; the inferior limb on the same side was affected with the like phenomena, but less violently; the speech was also somewhat impeded. The menses appeared twice during the month of December. Soon the sight of the left eye was disturbed, contractions then attacked the whole of the muscular system of the left side, and finally the whole body was seized with all the symptoms of confirmed St. Vitus's dance.

The left arm had completely lost its sensibility, and the patient is extremely irritable, the least contradiction bringing on the paroxysms.

On the 3rd of January, M. Dalmas prescribed a bleeding from the foot.

6th. The convulsive movements are less

frequent on the left side. A sulphur bath ordered.

7th. The movements of the arm and left thigh are rather more marked; the right side, however, is more tranquil; pulse full and frequent.

Since the 8th, sulphur baths, and four grains of aloes in two pills, have been prescribed. On the 16th a considerable amelioration has been observed. The involuntary movements are trifling, but return from time to time, especially when the patient is contradicted.

On the 28th of January she left the hospital perfectly well, after having been in it twenty-three days.

Excision of a Tumour from the Anus—Abundant Suppuration stopped by the use of Créosote.

The tumour from which this patient suffered was situated on the left side of the rectum, immediately above the sphincter ani, and was about as large as an egg, hard, irregular, very painful, and adherent to the intestine and to the sphincter muscle; a sinus communicating with this tumour opened externally at the thick part of the buttock, and gave issue to a yellow serous liquid. On the 1st of November, with M. Perronneau; Dr. Bertholot removed this tumour, taking away at least a third of the sphincter, and half of the left wall of the anal extremity of the rectum, which was adherent to the tumour; as the disease extended as far back as the free edge of the larynx, it was necessary to enlarge the incision. After the operation two twisted sutures were used to retain the divided parts in contact, and the patient was put upon low diet; she went on well for a month afterwards, but, in consequence of the low diet and the excessive suppuration, she was reduced to a state of great weakness, and it was observed that the wound cicatrised very slowly. By applying a solution of the créosote, or immediate principle of tar water, to the wound, the suppuration diminished, the cicatrisation now proceeded very rapidly, and in twenty-seven days' time was perfectly healed.

HÔTEL DIEU D'AIX.

(Bouches du Rhone.)

Birth of a Monstrosity.

A woman, who had previously given birth

to three well formed infants, was confined on the 11th of September, 1833, and gave birth to a monstrosity, which was carefully examined by M. Bizot, and presented the following appearances. The head appeared to be in a normal state; the chest was contracted, and did not contain any viscera, except the thymus gland, the lungs and the heart being found in the abdomen; one of the inferior limbs had the heel in front, on the other leg it was behind, but the foot was twisted, and, from the disposition of the toes, showed that although placed on the left leg it belonged to the right side. There was neither perinæum, anus, scrotum, penis, nor any of the genital organs, but in place of the latter there was a small fissure of short extent, capable of admitting a sound. The liver was flattened, and adherent to the stomach, which was continuous with the duodenum as usual; this portion of the small intestines terminated in a cavity, into which also opened the bladder; no other traces of intestines were found, and the spleen and kidneys were also wanting; the pubis was separated by an interval of an inch, and the bones of the pelvis were much distorted. The nervous system of the brain was in a healthy state, but the ganglions of the great sympathetic were not examined.

British Hospital Reports.

ST. GEORGE'S HOSPITAL.

Disease of the Lip.

PHILIP PHILLIPS, æt. 60, was admitted with this affection. It has the appearance of an ulcerated sore, and is situated in the centre of the lower lip, of the size of a large nut, and having a granulated appearance. It is hard, and indurated in its texture; its surface is nearly flattened, and its edges of a purplish colour. He has had no medical or surgical advice for it up to the present time, and his general health has always been and still is in a very good state. He is unable to assign any cause for the origin of this affection; the only history of it that he can give is, that about seven months since he perceived a minute lump in the lip, which lump has been gradually increasing in size ever since until within the last six weeks, since which time it has remained stationary. He was ordered

R. Decoct. cinchonæ, 3 xj.

Liquoris arsenicalis, ℥ iij.

Liquoris potassæ, ℥ xxv.—Misce, fiat haust. ter in die sumendus.

Lotio nigra parti affect. applicand.

Shortly after his admission a triangular incision was made on the lip, which included the diseased part, and the edges were drawn together by ligatures. Some days after the operation the parts where the ligatures were applied assumed the appearance of ulceration; they were in consequence removed, and strapping and plaster applied in their stead. The ulcerated portions still had a suspicious-looking appearance, and the submaxillary glands became enlarged and painful. These appearances, however, subsided in a few days, the painful tumefaction of the glands decreased, and he left the hospital quite well in a few weeks.

Tumours over the Body.

A man, named Thomas Barnes, was admitted into Oxford Ward a few days since under the care of Mr. Brodie, having been troubled for some time past with the growth of various tumours over his body. On being examined, they were found to be of various sizes, structure, and consistence. They were situated principally on the arms and legs, and one of them bore a resemblance somewhat to a node. The man could give no precise time as to the period of their first appearance, nor any cause which might have been likely to produce them. Their average size was that of a large walnut, and they were generally moveable under the skin, and not very hard to the touch. They gave no uneasiness, neither did they cause any pain when touched or handled. The patient's general health was remarkably good.

Mr. Brodie remarked, that, as far as his memory would serve him, he had only met with two cases whose characteristic symptoms at all approached to the one now before him, and these derived much benefit from the use of the *liquor potassæ* internally. The patient was therefore ordered to take liquor potassæ 3 j. three times daily in a glass of fresh small beer.

Mr. Brodie observed, that, with reference to this medicine, he had employed it in a vast number of cases of tumour either internal or external with very great success. It would frequently disperse abdominal tumours, the precise nature of which could not be accurately ascertained. A gentleman here asked Mr. Brodie whether it would not be worth while to try the value of this medicine in those cases of unusual and unnatural accumulation of fat in different parts of the body which sometimes occur. Mr. Brodie answered that it would be a remedy well worth trying in such cases. A man servant came to the hospital, some years since, as an out-patient under Mr. Brodie. He had two large pendulous masses of fat occupying the anterior surface of the neck, between the lower jaw and upper part of the chest, and posteriorly covering the nuchæ. This abnormal growth was a great calamity to him, as, from his appearance, no one would ever engage him as servant.

He took the liquor potassæ in doses of from ʒj. to ʒiiss. ter in die for some time, and the growth of this swelling slowly diminished down to such a size as to prove no longer a source of uneasiness or disfiguration to him. Some time afterwards Mr. Brodie saw this man, and the tumour at the fore part and back of the neck had so nearly disappeared as to enable him to follow his usual occupation. Mr. Brodie had another case nearly similar to the above, in which the same good results followed the internal exhibition of the liquor potassæ. There also sometimes arise different collections of fat under the skin, unequal in size, and having no defined margin or edge; and in these cases the exhibition of this medicine is equally useful.

The patient has continued taking the liquor potassæ; no material benefit has yet resulted from it, there not having been sufficient time. He complains that the medicine "binds him up," and he was therefore ordered

*R. Pilulæ hydrargyri,
Extracti colocynthid. comp.,
Extracti hyoscyami, aa ʒi. misce. Fiat
massam, in pilul. xij. divid., quarum
sumat i. o. n. h. s.*

Mr. Brodie observed, that this prescription was a very useful one, and of particular service to patients who were taking the liquor potassæ. The medicine has agreed with this patient very well hitherto, but no decided effect has as yet resulted in regard to the diminished growth of the tumours. He does not suffer in his general health, and his bowels are purged occasionally by a dose of house physic.

This case is an interesting one in many points of view, and we shall take notes of and report its future progress.

WESTMINSTER HOSPITAL.

Calculus Vesicæ—Lithotripsy.

Baron Heurteloup's very interesting, but difficult case of stone in the bladder (which we noticed on former occasions in this Journal) has proceeded very favourably, all the various obstacles which he was compelled to encounter being taken into consideration. The present is, we believe, one of the most obstinate cases which it has ever fallen to the Baron's lot to encounter. The nucleus of the stone, contained in the bladder, was of the most intense hardness, and for a long time resisted the most violent blows of the percuteur. There is, however, every reason to believe that it has been at length pulverised, and it is expected that one more operation will effect a cure. The patient (with the exception of being minus a little flesh) does not appear to have suffered in his general health, and he is impressed with a firm confidence in the efficacy

of the operation. His bowels have been kept well opened, and he takes opium every night.

A very extraordinary circumstance, which occurred in this case a short time ago, may be mentioned here. The patient, when in the act of voiding urine, suddenly felt a very painful sensation in the urinary passage, just close to the orifice. On directing his attention to the part, he discovered a large stone of irregular dimensions, firmly settled in the urethra, within about three-quarters of an inch of the orifice. Having made several efforts to expel it, without success, Mr. Finch (the late house-surgeon of the establishment) was immediately sent for, who succeeded in extracting the stone with a dressing forceps. The size of the stone excited the astonishment of all present.

ST. THOMAS'S HOSPITAL.

Neuralgia et Erysipelas.

William Smith, æt. 32, admitted into William's ward, under the care of Dr. Elliotson, January 13th, 1834. Works at the docks; of good general health; subject to slight attacks of rheumatism for several years; within the last twelve months has complained of neuralgic pains, situated principally in the left leg and thigh, and the right arm and shoulder; pains are not of equal intensity; they are often felt shooting up the limb, in the course of the principal nerves. Ordered ferri carbon. ʒij. 6iis.

14th. Pains are somewhat abated.

20th. This morning he was attacked with shivering, and a blush of redness has surrounded the right eye-lid; bowels were opened yesterday by a dose of rhubarb and calomel. Ordered V.S. ad ʒxvj.; lot. frigida faciei applicanda; omit ferri carb.

21st. The redness has extended to the right ear which is much swollen, and to the side of the face; pulse not so full; no thirst. Ordered V.S. ad ʒx., abrad. capillitium; empl. lyttæ amplum nuchæ.

22nd. Blood buffy, but not cupped; erysipelas has spread towards the occiput; slightly rambling in his conversation.

23rd. Face more inflamed; bowels confined. Ordered hirud. xvj. faciei; calomel., gr. vj. statim.

24th. Bowels have been well opened; erysipelas has ceased to spread; occasionally rambles in conversation; the redness is less about the face, but more in the neck. Ordered Hirud. xij. collo.

25th. Is much better to-day; quite rational; redness not extended, and seems disposed to die away. A ring of nitrate of silver has been carried around the inflamed part of an inch in breadth.

28th. Erysipelas is diminishing.

Feb. 4th. Complained yesterday of cough and pain in the chest, and for which a blister

Repet. med. nuperrimè prescripta.

4th. From the time of the application of the acid the part has put on a better appearance, looking, even as early as the next day, much more clean and healthy : it has gradually contracted, so that at present there is only a very small place remaining to be healed.

Continue the use of the balsam of Peru, as also of the last prescribed medicine.

11th. Since the last the part has by degrees put on a more irritated appearance, the tendency to spread recommencing, therefore the strong acid was again applied. Bowels very much confined; ordered to discontinue the iodine, and take

Pil. colocynth. c. cal. gr. xv. h. s.

Haust. gentianæ c. sennâ omni mane.

16th. The application of the acid produced the same beneficial effects as when first employed; however, as there still remained a small place between two of the projections which retained its angry character, the acid was once more used.

Perstet in usu haust. gentianæ c. sennâ.

22nd. Since the last application of the acid the part has almost entirely healed, there being now only a very minute spot to heal.

Mr. Mayo explained that there were two forms of the disease, one affecting persons of a full plethoric habit, attended with acute pain, and running a rapid course, and which was to be treated by bleeding; the other occurring in persons of a weaker habit, being slower in its progress, attended with much less pain, and best treated by the topical application of strong nitric acid.

THE

London Medical and Surgical Journal.

No. 112.

SATURDAY, MARCH 22, 1834.

VOL. V.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXXI., DELIVERED APRIL 3, 1833.

GENTLEMEN,—In the time of the French Academy of Surgery, about half a century ago, it was customary to employ the trephine, or rather the trepan, in almost all cases of fractured skull, not merely for the removal of any urgent symptoms present, but with the view of *preventing their occurrence at all*. The absurdity of the latter doctrine received a very complete exposure from the facts and observations published by the late Mr. Abernethy, whose investigations into this difficult part of surgery contributed very essentially, as I think, to its improvement, more especially by showing in what cases the application of the trephine might do good, and in what instances the operation should not be undertaken. Even at the present day his advice is sometimes neglected, for I am continually hearing of persons being trephined under circumstances in which, according to the principles established by his researches, they cannot possibly be benefited by the removal of any part of the cranium. As far as I can judge, the nature of the symptoms actually existing should here be your guide; and, so far from admitting the wisdom of the old rule of trephining in anticipation of symptoms which are only apprehended, but may never occur, I should say that the plan is altogether contrary to the dictates of reason and experience. As Mr. Abernethy observed, if the brain will, in the first instance, bear a certain degree of pressure without ill consequences, whether from fracture or effusion—if it will, at first, bear it without the production of urgent symptoms, or irritation of the dura mater by the inequality of a fracture, why should it not continue to do so subsequently? It is said, however, that when the cranium has been

struck with a sharp or angular body, the inner table is almost always splintered, and that such a case is a sufficient warrant for the application of the trephine, *without the presence of a single bad symptom*, or any disturbance of the sensorial functions; and that the operation should be done before inflammation has had time to come on. If you were certain that the inner table had been splintered, and if the symptoms were such as to indicate pressure on the brain from that cause, or an effusion of blood, the operation would be justified; but, without knowing even that such splintering exists, and without a single bad symptom denoting pressure on the brain, the plan of applying the trephine is not, as far as I can judge, at all advisable. It cannot be vindicated on any sound principles. Supposing the scalp were wounded, and the fracture of the skull comminuted, you would of course extract all the loose fragments, for they are already detached, and might cause irritation of the dura mater. This practice would be conformable to the general rules relative to the treatment of all wounds, wherever situated. But, if the pieces of bone were not completely detached, so that you could not remove them without an operation, and no bad symptoms existed, I should incline to the opinion of those surgeons who do not recommend an operation under these circumstances. Here is a skull in which a comminuted fracture happened; as there were no urgent symptoms the surgeon did not remove the fragments, yet the patient recovered in a favourable manner. I do not bring forward this fact to encourage you to leave loose pieces of the skull unremoved. I believe it is generally most advisable to take them away, particularly if the scalp be already wounded.

One consideration which influences me in defending the principle, that the trephine should not be used in injuries of the head, unless bad symptoms actually exist, and are of that description which may be relieved by this measure, is, that the operation itself—viz., the removal of a portion of the skull, and the exposure of the dura mater, are proceedings attended with some considerable risk of bringing on bad and even fatal consequences. The

late Mr. Ramsden was rather fond of operating; and I remember very well two cases in which he tried what the trephine would do for the relief of a long-continued fixed pain at one part of the head. A piece of bone was sawn out in each case; inflammation of the dura mater ensued; and in two or three days each patient fell a victim to the experiment.

Then, gentlemen, I must remind you, that the removal of a portion of cranium is often followed by a gradual protrusion of the brain through the aperture—that kind of swelling which is called *hernia cerebri*, and which almost always has a fatal termination.

Wounds of the Brain.—Many fractures with depression produce a laceration of the membranes, and even of the substance, of the brain. Modern experience proves, that this organ, important as are its functions, is frequently wounded without the event being immediately productive of those perilous symptoms which might be expected; but there is a difference in this respect, the reason of which is not at present satisfactorily understood. In some cases a comparatively slight wound of the brain gives rise to severe and rapidly fatal consequences; while in others, the same degree of injury, as far as can be ascertained, occasions no serious symptoms. However, I believe the history of this part of surgery will warrant me in representing wounds of the brain as generally attended with vast danger; and that, even if no bad symptoms occur directly after the accident, they mostly come on and prove fatal afterwards. Paroisse gives an account of twenty-two French soldiers, from whose skulls portions of bone with the scalp and slices of the upper part of the brain had been separated by sabre wounds. All these men ultimately died; but at first they had no bad symptoms, and actually performed a journey of ninety miles after the receipt of their wounds, one half of which distance they travelled on foot.

A French soldier was wounded at the battle of Waterloo: a musket-ball entered at the anterior portion of the squamous suture, lodged in the substance of the brain, and on the fifth day, after an enlargement of the wound, and the removal of several fragments of bone, it was extracted from the posterior lobe of the right hemisphere of the brain, where it had rested upon the tentorium. Headach and partial deafness of the right ear were the only bad symptoms. A recovery took place.

Gentlemen, you may be called upon to perforate the cranium for the removal of balls lodged within its cavity. Larrey relates some extraordinary examples of this practice; and it was he who first suggested the necessity of sometimes making a counter-opening in the bone for the accomplishment of this purpose, when the ball had passed to some point of the surface of the brain remote from the opening by which it had entered. He introduces an elastic gum catheter along the track of the ball, and makes a perforation with a trephine

over the part where he feels that it is lodged. Now, one of these histories is very curious; for after having removed a portion of the skull with a trepan, he took out an iron ball, that weighed seven French ounces, which was lodged upon the anterior lobe of the right hemisphere and against the orbital process and spine of the os frontis. The patient suffered a painful sense of weight in his head; and whenever he inclined it backward he was seized with syncope. Here, also, the case ended in the recovery of the patient.

You will find in the memoirs of the French Academy of Surgery various recoveries from most serious injuries of the brain; such cases as would *a priori* have been regarded as completely hopeless. If you look over the annals of surgery, you will be able to find numerous cases, in which the patients were cured, notwithstanding the brain had not merely been wounded, portions of it torn away, or separated. You may find, in one of the volumes of the *Médecinal and Chirurgical Transactions of London*, the particulars of the case of a boy, through whose frontal bone the linch-pin of a gun was driven with such violence, that it lodged in the anterior lobe of the brain. Directly after the injury, he walked several hundred yards, and then fell down, and was seized with convulsions. No suspicion was at first entertained of the passage of a foreign body into the brain. Venesection and other antiphlogistic measures were put in practice; and on the following day, the urgent symptoms had abated. The boy was treated on this system until the 27th day, when a piece of iron was noticed at the bottom of the wound, and extracted. It proved to be the linch-pin of a fowling piece, a substance of considerable size and weight. A cure ensued, with the exception of an amaurosis of one eye.

Gentlemen, in the treatment of injuries of the head, attended with a wound of the dura mater, or substance of the brain itself, if no particular symptoms or circumstances immediately demand the trephine, your chief reliance must be upon rigorous antiphlogistic treatment; the same plan as already advised for fractures unattended with urgent symptoms of compression. The external wound itself is to be treated on common principles; it is to be made clean, foreign bodies, or fragments of bone, are to be taken out, and its sides brought together.

Such cases commonly end fatally; but you must not absolutely despair of them, for the injury, and even a considerable loss of substance in the upper part of the hemispheres, may occur, as we find in the cases which I have quoted, without being necessarily fatal, or even productive of very alarming symptoms.

Wounds of the dura mater and brain are sometimes followed by *hernia cerebri*, which then often appears to have a considerable share in occasioning the patient's death.

Compression of the brain may arise from fracture with depression, from an extra-

collection of blood within the cranium, or from a collection of matter in the substance of the brain or between the inner table and the dura mater, in consequence of previous inflammation, the symptoms of which must then precede those which usually accompany the injurious effect of pressure on the brain. You may have also compression of the brain by the lodgment of balls within the cranium, or by the formation and growth of tumours. When such pressure exists, it cannot be expected that the symptoms will be alike in all cases, because the pressure not only differs in respect to its cause, its degree, and its situation, but it differs also in another important point of view, namely, that relating to the kind and quantity of other injury, or mischief, with which such pressure may be conjoined. For, gentlemen, you will find in practice, that every case of pressure, following external violence, is not so clear as many writers would lead you to suppose; and that you will not always have mere pressure to deal with, but often pressure combined with concussion, with inflammation, or with a wound or laceration of the membranes or substance of the brain. In short, you will frequently have to exercise your judgment on what may be called *mixed, or complicated cases*, in which the symptoms do not correspond altogether to those either of compression, concussion, or inflammation singly. Yet, if you understand the general character of the symptoms resulting from each of these states, you will be in a great measure qualified to judge of the effects likely to be the result of their happening to be co-existent.

It might be thought that apoplexy would give us the best illustration of the symptoms of simple compression of the brain; yet this is perhaps not precisely the case, because apoplexy is often preceded by disease of the brain; and at all events as good an illustration of them is afforded by certain cases, in which after the receipt of a blow on the head the patients recover from the stunned state, immediately following the blow, and shortly afterwards begin to labour under the effects of an effusion of blood, gradually going on within the head.

Gentlemen, I will next endeavour to explain to you the *symptoms of compression of the brain*. These will be *headach, stupor, and drowsiness*; and while the quantity of effused blood is small, they may be the chief symptoms. Afterwards, when it increases, and the pressure on the brain is greater, there will be a *loss of all sensibility, and of all power over the voluntary muscles*. The eyes will remain half open, the retina will be perfectly insensible, the pupils will generally be dilated, and the iris quite motionless, even when a candle is brought close to the eye. You may pinch or prick the patient, and he is perfectly unconscious of it: the bladder, being paralytic, cannot empty itself; or its sphincter and that of the anus being in this state, the urine and feces come away involuntarily. The

pulse is slow, and respiration carried on with difficulty and a stertorous noise.

The observations, already delivered respecting mixed or complicated cases, will let you at once perceive that, even when compression of the brain exists, and this in an unequivocal manner, the symptoms may be modified by the particular complications attending it. Thus, frequently, one pupil may be contracted, and the other be dilated; or the patient may be paralytic on one side, and convulsed on the other. Perhaps convulsive twitches of the muscles are rather symptoms of laceration of the brain, than of simple compression. They often attend fractures with depression.

In compression, there is usually no sickness and no vomiting. This fact is well exemplified by cases, in which the patient is free from these symptoms until he has been trephined, and then the removal of the pressure is sometimes immediately followed by the rejection of the contents of the stomach.

Another fact, which deserves notice, is that, when pressure exists only on one side of the head, the paralysis generally manifests itself in parts on the opposite side of the body. Complete hemiplegia is much more rarely the consequence of accidental injuries of the head, than of apoplexy; a difference, perhaps, referable in these cases to the difference in the situation of the effused blood.

With respect to paralysis, though it is a common symptom of pressure, various facts on record tend to prove that it may also arise from concussion. The observations of Desault, Dupuytren, and, if I remember right, those of Mr. Brodie, all corroborate this statement.

Gentlemen, you cannot pay too much attention to one circumstance, frequently throwing considerable light on these cases. I allude to the patient sometimes *recovering his senses, after having been stunned by the blow, and then relapsing into a drowsy condition, which is soon followed by all those symptoms already specified as denoting compression of the brain*. That these symptoms cannot depend upon concussion is manifest; for then the patient *would not have regained his senses for a time*, a fact, proving that the stunning, or the immediate effect of the concussion, had subsided. That the symptoms cannot depend upon a depressed fracture is equally manifest, because the patient *would have been senseless from the first, and have continued so without remission*. That the same symptoms cannot depend upon the lodgment of matter beneath the skull is certain, *because there has not been time enough for inflammation and suppuration to occur*. The real cause of the return of the loss of sense, then, under these circumstances, becomes tolerably evident; and is accounted for by the extravasation continuing slowly to increase, and to produce more and more pressure, and its usual consequences, notwithstanding it had not advanced sufficiently

at first to prevent the return of the mental faculties, on the subsidence of the immediate effects of the concussion which the brain sustained.

When no interval of sense takes place, but the patient lies insensible and motionless from the first, then you can only form a judgment of the cause of this state of the system, by the consideration of other symptoms. Frequently, cases of this kind are particularly unfavourable, as being complicated ones, combining sometimes concussion and compression together, and not only these evils, but a wound or laceration of the brain, and even a fracture at the base of the skull, or elsewhere.

Extravasations of blood between the dura mater and base of the cranium are mostly fatal. When the blood lies between the dura mater and tunica arachnoides, it is often widely diffused, so as not to admit of being effectually discharged. When situated between the cranium and the dura mater, however, it is circumscribed and may be discharged by a perforation of the bone.

There is frequently extreme difficulty in forming an opinion about the situation of extravasated blood, when symptoms indicate its existence. Generally we know not whether the blood lies on the dura mater or in a deeper situation, or under what part of the cranium. Now, if the symptoms be urgent, the rule is, that *you are to be guided in the choice of a place for the application of the trephine by any mark of violence on the scalp, or any wound, or fracture, showing the part on which the violence has acted*; for it is directly under it, that the extravasation is frequently situated, though not constantly. You should also consider on which side of the body the paralytic effects show themselves, as the probability is, that the pressure is on the hemisphere of the brain of the opposite side.

Sometimes there is no mark of external violence on the head—no wound to guide you—no restriction of paralysis to one side of the body—no interval of sense. Here circumstances are desperate, and you have no choice, but either that of trusting to means calculated to stop the further effusion of blood in the head, viz., cold washes and venesection, or that of perforating the cranium without any kind of clue to the situation of the effused blood.

Under these circumstances, the generality of surgeons would be content with bleeding and antiphlogistic treatment; while others, knowing that when a considerable quantity of blood is effused on the surface of the dura mater, it is generally poured out from the middle meningeal artery, might feel disposed to trephine in the track of that vessel. Here is a skull, in which you see a fissure crossing the groove for the principal artery of the dura mater. Were there any guide to the side of the head on which the extravasation lay, this bold measure might be warranted; but, I believe, the generality of surgeons would rather confide in antiphlogistic treat-

ment. Often the blood is on both sides, and sometimes not only so, but not under the part struck.

When dangerous compression of the brain arises from a fracture with depression, the indication is to elevate or remove the portion of bone forced below the rest of the cranium. For this purpose, you are to adopt certain modes of proceeding, which will be explained when I show the operation of trephining.

Also *when suppuration occurs on the surface of the dura mater, and produces urgent symptoms of pressure*, the same operation may be indispensable; but this case is generally not one of simple compression,—it has been preceded and is usually still accompanied by inflammation under the cranium, affecting not merely the dura mater, perhaps, but the brain itself.

Gentlemen, we have before us two preparations, which I will send round for your inspection. One is a cranium, in which you may observe that a small exfoliation has commenced, in consequence of suppuration on the dura mater. It is one of Pott's cases, as they are called, in consequence of his having particularly described them. In this instance, the trephine was applied, and the dura mater found red and spongy. But, gentlemen, the case was not one of simple pressure; for, besides the disease of the dura mater, the next preparation, taken from the same patient, exhibits a deeply-seated abscess in the brain, about an inch below that part of the skull which is undergoing exfoliation. You may also plainly see the thickened dura mater in that situation.

The patient, before exhibiting the symptoms of pressure, must have had those of meningeal inflammation,—he must have had severe pains in the head, shiverings, an accelerated pulse, and disturbance of the intellects, followed by coma, and loss of sense, and generally a puffy circumscribed tumour of the scalp, and detachment of the pericranium, corresponding to the extent of the abscess between the inner table and the dura mater. Or, if there were an external wound, its lips would have lost their vermilion colour, become pale, flabby, and swollen, and the discharge changed to a scanty foetid ichor.

Such a case calls for the immediate perforation of the bone, and rigorous antiphlogistic treatment, copious bleedings, leeches, the repeated exhibition of calomel and James's powder, or of saline purgatives joined with tartarised antimony, abstinence and quietude.

Let us next, gentlemen, notice *concussion of the brain*. This has many degrees, as you may readily conceive, when you recollect the great difference which exists between its two extremes, the slight transient stunning, the sudden effect of a moderate blow on the head, and that complete disorganisation, which, at the instant of the injury, permanently annihilates all the powers of life.

When the concussion is slight, a temporary stunning, and a degree of headach, followed

by acceleration of the pulse, vertigo, and sickness may take place; but in general none of these effects continue long if depletion be employed. However, in some examples, a very slight blow on the head will bring on inflammation of the dura mater, and this sometimes long after the accident, when all apprehension of danger has ceased.

When the violence applied to the head is greater, the patient is immediately stunned, his extremities become cold, his pulse is feeble, slow, and intermitting, his respiration difficult, but generally without stertor, and his sensibility and power of motion are entirely abolished.

This is the *first stage of concussion*, or the first effects produced by severe degrees of it. Such a state cannot last long, for the patient either dies in a very short time, or the effects, which I have been describing, gradually subside, and are succeeded by others, which may be said to constitute the *second stage of concussion*.

In this the pulse and respiration improve, and, though not regularly performed, are sufficient to maintain life, and to diffuse warmth over the extreme parts of the body. The nervous influence is also now so far revived, that if the skin be pinched the patient is conscious of the injury; but he lies in a dull stupid state, quite inattentive to slight external impressions. In proportion as the first effects of the concussion subside a little more, he becomes capable of replying to questions put to him in a loud tone of voice. As long as the stupor remains, the inflammation of the brain is moderate, but as the former abates the latter seldom fails to increase, so as to bring on the *third or inflammatory stage of concussion*.

In this *third stage*, if the eye-lids be opened, the patient will shut them again in a peevish manner; the pupils are contracted, and a strong light is very offensive. The patient is sleepless, talks much and incoherently, and if not restrained will get out of bed, and act with frantic absurdity. As the delirium increases the pulse becomes small, very quick, and even rapid; and, if the inflammation of the brain be not checked, suppuration, or effusion, will occur within the head, preceded by rigors, and the foregoing symptoms change into others, arising from the pressure of the fluid on the brain.

The dangers, then, of concussion depend upon its original violence, which may be such as to kill the patient at once, or upon the inflammation of the brain and its consequences, which often follows this kind of injury.

With respect to the sickness and vomiting, they are generally early symptoms, and seldom continue after the patient has recovered from the first shock of the accident.

Gentlemen, concussion and compression are often combined; and this fact will explain why the symptoms frequently have not the simplicity you might expect from some descriptions

given of them. Patients, who recover from severe degrees of concussion, sometimes remain variously and curiously affected by the accident during the remainder of their lives. Imbecility, loss of memory, and a marked change in the character are sometimes the permanent consequences. The patient may suffer loss of hearing, or partial paralysis. In consequence of an accidental concussion of the brain, a patient, previously a lunatic, has been known to recover his reason. In other instances, the patient, at first, can only remember circumstances with which the mind had been lately impressed, but afterwards recollects nothing but what happened in his childhood. Sometimes the effect is a total forgetfulness of a language, with which the patient was previously familiar. Mr. Liston attended a woman who recovered her hearing entirely from the accidental effects of a concussion of the brain. Last year I attended a lady in the Regent's Park, who met with a concussion of the brain from her horses taking fright and running away with the carriage till it came in contact with some iron railings: in this example, the patient has not the slightest recollection of having met with any accident in the Park; nor does she remember the circumstance of the horses galloping away with her, or the fall of her coachman from the box. During my attendance on her, with Dr. Pinckard, she never adverted to the injury of her head, but repeatedly to a slight burn of her neck, which she had met with two or three days before the other more serious injury.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833-34.

LECTURE XIII.

Jaundice from Gastro-Duodenitis—Researches of Broussais and Marsh—Without Hepatic Inflammation—Nervous Symptoms—Treatment—Yellow Fever—Its Occurrence in this Country—Predominance of Gastric Irritation in Warm Climates—Typhus Icterodes—Jaundice from Biliary Calculi.

GENTLEMEN,—We commence to-day with the consideration of that form of jaundice, which, taking *all* its cases into account, appears to be the most common. The pathological expression for this form of the disease is, that it is inflammation of the upper portion of the digestive tube, or in other words, that it is the result of a gastro-duodenitis. In this case an inflammatory affection of the stomach and duodenum acts sympathetically on the liver, and we have jaundice occurring independent of hepatic inflammation or mechanical obstruction to the flow of bile. This variety of the disease it is important you should be accurately

at first to prevent the return of the mental faculties, on the subsidence of the immediate effects of the concussion which the brain sustained.

When no interval of sense takes place, but the patient lies insensible and motionless from the first, then you can only form a judgment of the cause of this state of the system, by the consideration of other symptoms. Frequently, cases of this kind are particularly unfavourable, as being complicated ones, combining sometimes concussion and compression together, and not only these evils, but a wound or laceration of the brain, and even a fracture at the base of the skull, or elsewhere.

Extravasations of blood between the dura mater and base of the cranium are mostly fatal. When the blood lies between the dura mater and tunica arachnoides, it is often widely diffused, so as not to admit of being effectually discharged. When situated between the cranium and the dura mater, however, it is circumscribed and may be discharged by a perforation of the bone.

There is frequently extreme difficulty in forming an opinion about the situation of extravasated blood, when symptoms indicate its existence. Generally we know not whether the blood lies on the dura mater or in a deeper situation, or under what part of the cranium. Now, if the symptoms be urgent, the rule is, that *you are to be guided in the choice of a place for the application of the trephine by any mark of violence on the scalp, or any wound, or fracture, showing the part on which the violence has acted*; for it is directly under it, that the extravasation is frequently situated, though not constantly. You should also consider on which side of the body the paralytic effects show themselves, as the probability is, that the pressure is on the hemisphere of the brain of the opposite side.

Sometimes there is no mark of external violence on the head—no wound to guide you—no restriction of paralysis to one side of the body—no interval of sense. Here circumstances are desperate, and you have no choice, but either that of trusting to means calculated to stop the further effusion of blood in the head, viz., cold washes and venesection, or that of perforating the cranium without any kind of clue to the situation of the effused blood.

Under these circumstances, the generality of surgeons would be content with bleeding and antiphlogistic treatment; while others, knowing that when a considerable quantity of blood is effused on the surface of the dura mater, it is generally poured out from the middle meningeal artery, might feel disposed to trephine in the track of that vessel. Here is a skull, in which you see a fissure crossing the groove for the principal artery of the dura mater. Were there any guide to the side of the head on which the extravasation lay, this bold measure might be warranted; but, I believe, the generality of surgeons would rather confide in antiphlogistic treat-

ment. Often the blood is on both sides, and sometimes not only so, but not under the part struck.

When dangerous compression of the brain arises from a fracture with depression, the indication is to elevate or remove the portion of bone forced below the rest of the cranium. For this purpose, you are to adopt certain modes of proceeding, which will be explained when I show the operation of trephining.

Also *when suppuration occurs on the surface of the dura mater, and produces urgent symptoms of pressure*, the same operation may be indispensable; but this case is generally not one of simple compression,—it has been preceded and is usually still accompanied by inflammation under the cranium, affecting not merely the dura mater, perhaps, but the brain itself.

Gentlemen, we have before us two preparations, which I will send round for your inspection. One is a cranium, in which you may observe that a small exfoliation has commenced, in consequence of suppuration on the dura mater. It is one of Pott's cases, as they are called, in consequence of his having particularly described them. In this instance, the trephine was applied, and the dura mater found red and spongy. But, gentlemen, the case was not one of simple pressure; for, besides the disease of the dura mater, the next preparation, taken from the same patient, exhibits a deeply-seated abscess in the brain, about an inch below that part of the skull which is undergoing exfoliation. You may also plainly see the thickened dura mater in that situation.

The patient, before exhibiting the symptoms of pressure, must have had those of meningeal inflammation,—he must have had severe pains in the head, shiverings, an accelerated pulse, and disturbance of the intellects, followed by coma, and loss of sense, and generally a puffy circumscribed tumour of the scalp, and detachment of the pericranium, corresponding to the extent of the abscess between the inner table and the dura mater. Or, if there were an external wound, its lips would have lost their vermilion colour, become pale, flabby, and swollen, and the discharge changed to a scanty foetid ichor.

Such a case calls for the immediate perforation of the bone, and rigorous antiphlogistic treatment, copious bleedings, leeches, the repeated exhibition of calomel and James's powder, or of saline purgatives joined with tartarised antimony, abstinence and quietude.

Let us next, gentlemen, notice *concussion of the brain*. This has many degrees, as you may readily conceive, when you recollect the great difference which exists between its two extremes, the slight transient stunning, the sudden effect of a moderate blow on the head, and that complete disorganisation, which, at the instant of the injury, permanently annihilates all the powers of life.

When the concussion is slight, a temporary stunning, and a degree of headach, followed

by acceleration of the pulse, vertigo, and sickness may take place; but in general none of these effects continue long if depletion be employed. However, in some examples, a very slight blow on the head will bring on inflammation of the dura mater, and this sometimes long after the accident, when all apprehension of danger has ceased.

When the violence applied to the head is greater, the patient is immediately stunned, his extremities become cold, his pulse is feeble, slow, and intermitting, his respiration difficult, but generally without stertor, and his sensibility and power of motion are entirely abolished.

This is the *first stage of concussion*, or the first effects produced by severe degrees of it. Such a state cannot last long, for the patient either dies in a very short time, or the effects, which I have been describing, gradually subside, and are succeeded by others, which may be said to constitute the *second stage of concussion*.

In this the pulse and respiration improve, and, though not regularly performed, are sufficient to maintain life, and to diffuse warmth over the extreme parts of the body. The nervous influence is also now so far revived, that if the skin be pinched the patient is conscious of the injury; but he lies in a dull stupid state, quite inattentive to slight external impressions. In proportion as the first effects of the concussion subside a little more, he becomes capable of replying to questions put to him in a loud tone of voice. As long as the stupor remains, the inflammation of the brain is moderate, but as the former abates the latter seldom fails to increase, so as to bring on the *third or inflammatory stage of concussion*.

In this *third stage*, if the eye-lids be opened, the patient will shut them again in a peevish manner; the pupils are contracted, and a strong light is very offensive. The patient is sleepless, talks much and incoherently, and if not restrained will get out of bed, and act with frantic absurdity. As the delirium increases the pulse becomes small, very quick, and even rapid; and, if the inflammation of the brain be not checked, suppuration, or effusion, will occur within the head, preceded by rigors, and the foregoing symptoms change into others, arising from the pressure of the fluid on the brain.

The dangers, then, of concussion depend upon its original violence, which may be such as to kill the patient at once, or upon the inflammation of the brain and its consequences, which often follows this kind of injury.

With respect to the sickness and vomiting, they are generally early symptoms, and seldom continue after the patient has recovered from the first shock of the accident.

Gentlemen, concussion and compression are often combined; and this fact will explain why the symptoms frequently have not the simplicity you might expect from some descriptions

given of them. Patients, who recover from severe degrees of concussion, sometimes remain variously and curiously affected by the accident during the remainder of their lives. Imbecility, loss of memory, and a marked change in the character are sometimes the permanent consequences. The patient may suffer loss of hearing, or partial paralysis. In consequence of an accidental concussion of the brain, a patient, previously a lunatic, has been known to recover his reason. In other instances, the patient, at first, can only remember circumstances with which the mind had been lately impressed, but afterwards recollects nothing but what happened in his childhood. Sometimes the effect is a total forgetfulness of a language, with which the patient was previously familiar. Mr. Liston attended a woman who recovered her hearing entirely from the accidental effects of a concussion of the brain. Last year I attended a lady in the Regent's Park, who met with a concussion of the brain from her horses taking fright and running away with the carriage till it came in contact with some iron railings: in this example, the patient has not the slightest recollection of having met with any accident in the Park; nor does she remember the circumstance of the horses galloping away with her, or the fall of her coachman from the box. During my attendance on her, with Dr. Pinckard, she never adverted to the injury of her head, but repeatedly to a slight burn of her neck, which she had met with two or three days before the other more serious injury.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XIII.

Jaundice from Gastro-Duodenitis—Researches of Broussais and Marsh—Without Hepatic Inflammation—Nervous Symptoms—Treatment—Yellow Fever—Its Occurrence in this Country—Predominance of Gastric Irritation in Warm Climates—Typhus Ictericus—Jaundice from Biliary Calculi.

GENTLEMEN,—We commence to-day with the consideration of that form of jaundice, which, taking *all* its cases into account, appears to be the most common. The pathological expression for this form of the disease is, that it is inflammation of the upper portion of the digestive tube, or in other words, that it is the result of a gastro-duodenitis. In this case an inflammatory affection of the stomach and duodenum acts sympathetically on the liver, and we have jaundice occurring independent of hepatic inflammation or mechanical obstruction to the flow of bile. This variety of the disease it is important you should be accurately

acquainted with, as it is not only exceeding common in temperate climates, but because I believe it is a great cause of mortality in warm countries, and that the yellow fever of the tropics is reducible in a great measure to this form of disease. In other words, that the cause of the yellowness and many other of the symptoms is to be referred to an intense irritation or inflammation of the digestive tube, with a predominance of that irritation in its upper portion.

The jaundice which depends upon gastro-duodenal inflammation was first accurately described by Broussais. Dr. Marsh has also made many valuable additions to our knowledge on this subject in his paper on jaundice, published in the fifth volume of the Dublin Hospital Reports. You will find too that in a case of jaundice described by John Hunter, he suggests the possibility of its being preceded by inflammation of the duodenum. But I believe we are chiefly indebted to Broussais for our first correct notions of the pathology of this disease, and for its scientific and successful treatment.

The disease may occur in the acute form, or it may come on in a slow insidious manner; but in either case, as far as my experience goes, it is always accompanied by symptoms referable to a morbid state of the mucous membrane of the intestines. Dyspeptics and individuals subject to diarrhoea are liable to it, but it may also attack strong and healthy persons from the two following causes. A man is exposed to considerable heat, his body is bathed in perspiration, he experiences some degree of lassitude, and is very thirsty; in this state he takes a large draught of cold water. In a few hours afterwards he begins to feel uneasy and complains of being unwell; he gets shivering, nausea, thirst, and fever, and this fever and thirst with bilious symptoms (as they are called) continues for two or three days, when some morning on awaking the patient is surprised to find himself jaundiced. The same thing may happen as a consequence of error in diet. A person eats at supper a quantity of indigestible food, next day he has vomiting and thirst, and in a day or two more jaundice appears. I may remark here that this indisposition of two or three days' standing is a very curious and interesting feature in the disease, and would seem to be connected with the progress of disease in the mucous surface of the stomach and duodenum. Jaundice from gastro-duodenitis generally occurs in this country under two varieties. The first is an extremely mild disease; it comes on with very slight and transient symptoms of constitutional or local derangement, it seldom prevents the patient from pursuing his ordinary avocations, and generally disappears without any trouble. The second variety is an extremely severe and frequently a fatal disease; between this and the former there are numberless shades and gradations.

Let us take a case of the more severe form

of jaundice. The cause of this, as I have already mentioned, is often the taking a copious draught of cold water, while the body is heated by exercise, or eating a quantity of indigestible food. The patient is indisposed for two or three days before the jaundice appears; he has nausea, vomiting, great thirst, loss of appetite, he complains of burning heat in the epigastrium, and there is some tenderness on pressure over the region of the stomach and duodenum. His tongue is foul, his bowels costive, his urine loaded, he has considerable prostration of strength, complains of vertigo and lowness of spirits, and is constantly sighing. There is always more or less febrile disturbance: in some cases the fever is ephemeral, and goes off in a day or two, in others it continues for a much longer period. When this fever continues beyond the second or third day, it is to be looked upon as an unfavourable sign, and you may expect that the case will be unmanageable and dangerous. There is another remarkable symptom on which I have had reason generally to found an unfavourable prognosis, *and this is a variation in the intensity of the yellowness.* In some cases you will find that to-day the countenance and skin are much less yellow, and this is always noticed by the patient, whose spirits are generally raised by the decline of the jaundiced tint, but in a day or two it becomes as deep as ever, and it may go on in this way, alternating from a faint to a deep tinge, and vice versa. This is an unfavourable symptom: it appears to indicate the repetition of inflammatory action in the intestinal tube, because each increase in the depth of the yellow tinge is accompanied by an increase of the epigastric symptoms. In such cases as this, the patient does not, as under other circumstances, shake off the disease and return to his usual habits; he lies in bed, and though he complains of no pain except when you make firm pressure on the epigastrium, still he is not at all improving; he tells you he is better, but he is still languid, and his appetite does not return. The stools are generally clay-coloured, but this is not a necessary consequence of jaundice, they are sometimes yellow, and I have seen them of a perfectly healthy appearance. The pulse, in most cases where the fever is ephemeral, returns in a few days to its natural standard; in some instances it is remarkably slow, and this state of pulse is to be regarded as an unfavourable symptom. Sometimes there is a slight degree of subsultus tendinum and delirium, and I must observe that you are never to forget that the early supervision of nervous symptoms in any form of this disease is always to be looked upon with suspicion. One of the most alarming complications, however, of this gastro-duodenal jaundice is the occurrence of coma during its progress, a symptom to which the attention of the profession was first strongly directed by Dr. Marsh. He has given several cases of jaundice characterised by this symptom, the man

forty of which resisted all the ordinary resources of medicine, and terminated fatally. I must confess, too, that I have never seen a case in which the coma was distinctly established terminate favourably. You should, therefore, when called to treat a case of jaundice, be always on the alert, and never allow any bad symptom like this to steal upon you, and it is gratifying to think that if you take this symptom in time you will, in all probability, be able to overcome it.

An extremely interesting paper on this coma occurring in jaundice will appear in the forthcoming number of the Dublin Medical and Chemical Journal, from the pen of Dr. Griffin of Limerick. He gives the details of some extraordinary cases, which you will find well worthy of an attentive perusal. Out of four cases in one family, which he attended, two died, who had become comatose at an early period; in the other two the affection of the brain was relieved by bleeding and other active measures. From this it would appear, that the mere supervention of coma is not necessarily followed by death, but that it is an exceedingly dangerous symptom when it comes on at an early period of the disease. It is very difficult to give a satisfactory explanation of this. Some persons think that it is attributable to the action of the bile on the blood which is circulating in the brain. This explanation would answer very well if coma was a symptom of constant occurrence; this, however, is not the case, and we must seek for some better reason. It is stated by some, that coma may be one of the consequences of the close sympathy which exists between the brain and liver. Dr. Griffin draws an analogy between the effects of suppression of bile in jaundice and suppression of urine in diseases of the kidneys, and thinks that the affection of the brain is of common occurrence in one as well as in the other. This analogy, however, is incomplete, for we have no case of complete suppression of urine without fever and other violent symptoms, but we have many cases of complete suppression of bile with very slight and almost inappreciable disturbance of the economy. It is very difficult, in the present state of medical science, to explain the coma of jaundice; all we know is, that it sometimes occurs, that it is a bad symptom, and must be met with great activity. I may mention one fact which seems to be strongly opposed to the analogy of Dr. Griffin. It will be proper to observe here, that Dr. Griffin does not advance this as an opinion, or advocate it as a theory; he merely offers it as a hint or suggestion, leaving it to others to decide the question. We are not, therefore, in examining this analogy, reasoning against any opinion of his. But with respect to this matter, the fact to which I allude is this—one of the worst cases of coma I ever witnessed occurred in a patient who had no suppression or retention of bile: the bile flowed freely into the intestines, the dejections were distinctly tinged

with it, and yet this man had deep jaundice and intense coma. We are still in want of a number of facts on this point; it is a subject which affords a large field for interesting enquiry, and Dr. Griffin deserves great credit for the philosophical and impartial manner in which he has brought his cases before the medical public.

When a patient dies of jaundice accompanied by this comatose affection, you are naturally anxious to ascertain the cause of death. Now what you will generally find is this: on opening the head you examine the brain accurately, but cannot detect any lesion of its substance or membranes; you then go to the stomach and discover there marks of vascularity; you open the duodenum and find it in a state of intense inflammation. I have seen many cases of this disease, in which the mucous membrane of the duodenum was highly engorged and almost black. It is said that this inflammation extends from the duodenum along the common biliary duct to the liver. I am not possessed of facts to confirm this assertion, but I have little doubt that, in the majority of cases, the jaundice is more the result of a mere lesion of innervation of the liver, than proceeding from any spread of inflammation along the ducts into its substance. Unless we can demonstrate this inflammation, it is idle to assume its occurrence. When you examine the liver, gall-bladder, and biliary ducts, you generally find them in the normal state. In a few cases the ducts have been found impervious from adhesive mucus: you will see in John Hunter's works a case of this kind, which occurred in a consumptive patient. You will find a great number of important facts, relating to the pathology of jaundice, in the commentaries upon his own pathological propositions by M. Broussais. I would also advise you to peruse Dr. Marsh's excellent paper in the Dublin Hospital Reports.

We come now to the diagnosis of jaundice depending upon gastro-duodenal inflammation. In the first place, we learn from the history of the case that the exciting cause has been some excitant of inflammation in the mucous surface, the ingestion of indigestible aliment, or taking cold water into the stomach while the body has been overheated. The next thing is the supervention of fever with gastric symptoms, and these being followed in two or three days by an attack of jaundice, *without any of the ordinary signs of hepatitis*. Here we have a disease excited by taking cold water while the body is heated, or by indigestible food, preceded by febrile disturbance with gastric symptoms, and unaccompanied by the symptoms or signs of hepatitis. When this combination of circumstances occurs, you make your diagnosis with great certainty, and set it down as jaundice depending on inflammation of the stomach and duodenum, and treat it accordingly. There are but two forms of jaundice accompanied by symptomatic fever,

the one under consideration, and that which is the consequence of hepatic inflammation, or other disease. It might be supposed that the tenderness of the epigastrium was caused by an affection of the liver, but by making an accurate examination you will be generally able to discriminate with certainty. You will find that the pain is less than that of acute hepatitis, that strong pressure gives pain, not in the region of the liver, but in that of the duodenum; you can ascertain by a manual examination and by the pleximeter, that there is no enlargement of the liver, that there is no remarkable dulness on percussion at the lower part of the chest on the right side, and when the fever is ephemerical, this will furnish you with much valuable assistance towards forming a correct diagnosis.

With respect to the treatment of this form of jaundice, in mild cases, where there is little or no fever (for fever is to be taken as a test of the severity of the disease), the patient very often gets well without any treatment, and the jaundice, after lasting a few days or weeks, goes off spontaneously. In all such cases a regulation of diet, keeping the bowels open by mild laxatives, and prohibiting wine, spirits, and other stimulants, will be found in general sufficient to remove all the symptoms. I wish, however, to impress upon you that it is of *the utmost importance to cut short this disease as soon as possible*. There is no use in letting it get ahead of you; and in every case where the symptoms are in any degree acute, and there is a degree of fulness and tenderness over the epigastrium, you will be culpable if you omit to apply leeches over the stomach and duodenum, and prescribe iced water, and every other means calculated to remove inflammation. If you allow it to go on to a certain length, if you allow fever to progress and coma to supervene, you will not be able to manage the case so easily. Never then omit the application of leeches the moment you have ascertained the existence of decided inflammation. Keep your patient's bowels open by enemata or by mild saline laxatives, regulate his diet carefully, prohibit all stimulants, and he will generally do well.

Many persons are in the habit of prescribing mercury in this disease. From my own experience I cannot say whether this is right or wrong; but I can state that I have seen a great many cases get well without it. But in cases where the symptoms are obstinate, and the stools continue white, I think you would be justified in giving mercury, even as far as to produce salivation. I must remark to you, however, that I have seen two cases in which it was found impossible to produce the free action of mercury in patients labouring under this disease. The exhibition of small doses of cream of tartar two or three times a day made into an electuary with some mild confection, I have found to be an excellent remedy in the treatment of this affection. In my lecture on dysentery, I mentioned some

facts which go to prove that this remedy seems to have great power in bringing down bilious discharges. In this form of jaundice I found cream of tartar extremely useful, and its exhibition is unattended with danger.

Now suppose you should meet with a case in which coma appears as an early symptom, what should your line of treatment be? Here you have to deal with a very threatening symptom, which, if neglected for any time, will, in all probability, bring on a fatal termination. You should therefore, on its first appearance, meet it with a corresponding activity; you should immediately have the head shaved, apply leeches behind the ears, blister the nape of the neck, and act smartly on the bowels by laxatives. It was by such treatment as this that Dr. Griffin saved his patients.

I wish here to make some observations on a very remarkable form of gastro-duodenitis, which was almost epidemic in this country some years ago, at least it occurred during the existence of an epidemic fever, and we had at that time a great many cases of it in hospital. It is a curious fact that the majority of these seemed to bear a distinct resemblance to the yellow fever of warm climates. This will appear somewhat extraordinary; but, when you have heard a statement of the facts, you will be inclined to think that these cases were nothing more or less than so many instances of the malignant yellow fever of the tropics. I shall read for you an account of the symptoms, as they were observed in numerous cases under the care of my colleague, Dr. Graves, and myself, in the Meath Hospital.

In the great majority of cases this disease was preceded by fever, in fact all the patients who exhibited this form of jaundice had been admitted as fever patients. After a longer or shorter period, without any premonitory indications, symptoms of intense irritation of the digestive tube set in, and advanced with a fatal rapidity. Most of the patients vomited frequently; there was great tenderness of the epigastrium and over the region of the small intestine; the tongue became black and parched; there was a violent pain in the belly, and a spasmodic affection of the abdominal muscles, which felt hard and knotted, and to which the nurses gave the name of *twisting of the guts*, a name which singularly agreed with the numerous intussusceptions found along the course of the small intestine after death. This state of suffering continued from one to four hours, and then the body became all over suddenly jaundiced. Then came another train of symptoms. With intense and universal jaundice the patients exhibited also extreme restlessness, tossing their arms about, and regarding their attendants with a look at once expressive of nervous suffering and despair. Some raved, had trembling and convulsive fits, and were totally unconscious of every thing passing around them; others preserved their intellect to the

last, but they had depicted in their countenances an agony and a despair which I shall never forget. General spasms were frequently observed; and many, on attempting to swallow, had spasms like those of hydrophobia. There was great irritability of the stomach; many vomited frequently, and in some cases the matter ejected bore an exact resemblance to coffee grounds. The pulse became low and fluttering, the extremities cold, the face pale and shrunken, and in some the nose assumed a purple colour, giving to the patient a truly horrible appearance. This change in the colour of the nose was preceded by extreme paleness; the part, at first, appeared as if it had been frost-bitten. Broad patches of a wax-like whiteness, elevated a little above the level of the skin, and somewhat resembling urticaria, having the same temperature as the rest of the body, were found on the following day to assume a reddish colour; and on the third day the redness was converted into dark purple. The toes were affected in a similar way; and in some of these cases the parts so affected sloughed and were thrown off. There is at present in this city a woman who lost the ala of the nose and one of the toes in this manner.

The phenomena observed on dissection were equally remarkable. Though the tenderness of the epigastrium was very great there was no trace of peritoneal inflammation; *neither was there in any case inflammation of the liver, and the gall ducts were found to be pervious in every instance.* The mucous surface of the stomach and duodenum and ileum were found in every case to present intense marks of inflammation, there were numerous intussusceptions along the course of the ileum, and the spleen was found to be large, soft, and pultaceous. There was no evidence of inflammation of the brain, but in the ventricles and at the base of the brain there was in some cases an effusion of yellowish fluid, and the membranes had a faint tinge of yellowness. In one case I found a remarkably dry state of the arachnoid. In one severe case there was a good deal of a substance resembling coffee grounds in the stomach, and the mucous membrane was soft and disorganised.

All the phenomena of this disease, the gastro-intestinal inflammation, the yellowness of skin, the enlargement and softening of the spleen, the rapid fatality and excessive prostration, seem to point out a strong analogy between it and the yellow fever of warm climates. In the writings of Rush and Lawrence you will find, that their description of the phenomena observed on dissection, would in a great degree answer for those of the cases which I have detailed. I may mention here, too, that in our cases the mortality was severe. We lost the first sixteen cases; and it was not until we fully ascertained the nature of the disease by dissection, that we began to save these patients. Then by free depletions, copious applications of leeches to the abdomen,

and the bold use of calomel and opium, we succeeded in a great number of cases. In some cases death took place in four, in others in six hours, in a few it was more prolonged. There is no epidemic on record in this city in which the same symptoms and the same rapid fatality were observed.

With respect to the analogy between this disease and yellow fever, it appears that in the latter affection the yellow colour depends upon the presence of bile in the blood. This is one point. Again, from the most accurate descriptions which have been given of the morbid appearances of yellow fever, it appears that in the majority of cases the liver has been found healthy; here is another point. In yellow fever also, inflammation of the stomach, duodenum, and intestines, is a matter of almost universal occurrence, as you will find by examining the works on yellow fever. In our cases we had all these circumstances; we had extreme tenderness of the epigastrium, and inflammation of the stomach, duodenum, and intestines; and in one severe case we had black vomit. All these circumstances, combined with the fatality, seem to prove that the cases which were under treatment in the Meath Hospital during the epidemic of 1826-27, bore a very striking resemblance to that species of fever which is supposed to exist only in warm climates. It is probable that if yellow fever should appear in temperate countries it would exhibit itself in the form of gastric fever, with some cases only of yellowness. Indeed it seems to be now very generally admitted that yellow fever has nothing peculiar in it, that it is the maximum of bilious or gastric fevers. We find that in proportion as we approach the warm latitudes, the digestive mucous membrane appears to take on a greater susceptibility of disease. Between the tropics it would seem as if morbid actions were chiefly thrown upon the viscera of the abdomen. Europeans who have resided there for any length of time acquire a yellow tinge, and many of them suffer from intestinal and hepatic inflammations. If we go northward we find the case to be the reverse; as we approach the colder latitudes we find the mucous membrane of the digestive tube acquires a greater degree of tone and vigour, that it is less susceptible of disease, and can bear much greater stimulation. The inhabitants of warm climates use a large proportion of vegetable food, they seldom indulge in the use of animal food or spirits. The Hindoo lives on rice, the Arab on dates and milk. But if we go northerly, we find the natives habitually using stimulating food and drink with impunity; indeed, it is wonderful to think what vast quantities of flesh, animal oil, and other stimulants the stomach of an Esquimaux or a Kamskatkan will bear without injury. There is no doubt that warm climates predispose to inflammatory affections of the digestive apparatus, and this seems to connect yellow fever with the ordinary form of gastro-

duodenitis accompanied with jaundice, or, in other words, a little more extent, a greater degree of intensity, and we may have the jaundice of this country converted into yellow fever. And it is fair to conclude that the *typhus icterodes* of temperate countries owes its danger not to the mere circumstance of jaundice existing, but to the greater degree of secondary gastro-enteritis which has produced that jaundice.

I shall now draw your attention to some other forms of jaundice. One of the most important of these is that which arises from the obstruction of the biliary ducts by calculi. It would be foreign to my purpose to enter into any discussion with respect to the formation of gall stones in a course of lectures like this; I shall therefore refer you for information as to their history and composition to the various treatises on animal chemistry. What we have to consider at present are the symptoms of the disease, the habit of body in which it is found to occur, and its mode of treatment. You see on the table numerous preparations of the various forms of this disease.

Gall stones are more commonly observed after the age of forty or fifty than before these periods; they are very frequently met with in persons of sedentary habits, and hence women are more subject to them than men. They are also liable to occur in persons who eat highly-seasoned indigestible meats, and take little or no exercise. It is stated that in England five sixths of the cases of gall stones occur in females. I do not know whether this proportion be exact, but the fact is established that they are more common in females than men. Biliary calculi may be found in three different situations, either in the substance of the liver, or plugging up the biliary ducts, or filling the gall-bladder. Here is a preparation, exhibiting the gall-bladder almost obliterated by the pressure of a number of those calculi within its cavity. Here is another specimen. You see the gall-bladder is contracted, and nearly filled up with biliary calculi; it also appears to be atrophied and reduced in size. Here is a remarkable specimen: you observe the gall-bladder, which is rather large, is completely filled with a vast calculus; its coats are also thickened, probably the result of inflammation. Here is another preparation of the gall-bladder, containing two moderately sized calculi.

Gall stones when lodged in the substance of the liver, or in the gall-bladder, may remain for a long time and accumulate prodigiously without producing jaundice. This has been frequently proved by the fact, that on opening the bodies of persons who have not had during life the slightest symptom of jaundice, the gall-bladder has been found completely filled up with these productions. But when any cause determines the passage of one of these bodies into the ducts, and that it is too large to pass freely, then the symptoms of icterus begin to make their appearance. We do not know

what it is that produces the attempt to discharge small biliary calculi through the ducts, but it is during this process that the dreadful symptoms of what has been by some called *hepatic colic*, are observed, and, supervening on these, the rapid occurrence of jaundice. Under such circumstances a train of phenomena presents itself, very different from that which characterises the jaundice depending on inflammation of the stomach and duodenum. The patient is suddenly attacked with violent pain in the epigastrium and right hypochondrium. The stomach sympathises, and we have nausea, cardialgia, and vomiting; the patient's sufferings are dreadful, and he refers his pain to the region of the gall-bladder. The abdominal muscles are thrown into spasmodic contractions, there are often convulsions and fainting fits, the extremities are cold, the body is bathed in perspiration, and the pulse is often hard and contracted, but seldom accelerated. This is a very remarkable symptom. Heberden says, that the pulse not being in quickness above the standard of health, with a sudden attack of pain in the region of the epigastrium, are diagnostics of this affection. "I have seen," says he, "a patient in this disease rolling on the floor in a state of violent agony, which I could not allay with nine grains of opium, and yet the pulse was as tranquil as if he was in a calm sleep." I can confirm the truth of this observation from my own experience. Here are the diagnostics: the pain is more intense than that which attends any form of inflammation, and yet the pulse is perfectly quiet; it occurs in persons not generally subject to spasmodic attacks; it is not preceded by constitutional symptoms; and is rapidly followed by jaundice, and absence of bile in the stools. Under these circumstances you may make a certain diagnosis.

Sometimes a tumour is formed in the right hypochondrium, which rises above the edge of the liver and gives a feeling of distinct fluctuation, marking the situation of the distended gall-bladder. In such cases as these the calculus is in the common duct, and the bile descends into the gall-bladder, from which it cannot escape, thus causing distention of that organ. This may go on until the distention becomes so great as to increase the size of the gall-bladder to such a degree, that, in some cases, it has been known to contain a pint of fluid; and cases have occurred in which it has burst and effused its contents into the peritoneum, causing violent peritonitis and death. This termination, however, is fortunately of very rare occurrence. I believe that some of the cases in which rupture occurred were those in which an emetic was given; and hence it is that many practitioners are afraid to give an emetic where this state of the gall-bladder has been ascertained or is strongly suspected.

Gentlemen, I shall continue this subject at our next meeting.

**PLAN OF A UNIVERSAL ASSOCIATION
OF APOTHECARIES IN THE UNITED
KINGDOM OF GREAT BRITAIN.**

BY ALEX. THOMSON, M.D. OF ST. JOHN'S, CAMB.

• *Eheu! Inter dicendum fugerit Invida ætus!*"

*Objects proposed to be accomplished by the
adoption of the following Plan:—*

To melt all those, having chemists' shops, without being members of an Apothecaries' Company, and all those members of the Apothecaries' Companies of the United Kingdom, either not practising medicine, or willing to abandon that practice for becoming members of the Society, into an harmonious whole, distinct from medical men and from druggists.

To reserve to the members of this Association the name of Apothecaries, and to the Company in general that of Apothecaries' Company of Great Britain.

To do away with the system of centralising chemical and pharmaceutical knowledge.

To furnish a stimulus to the members of this Association to keep up their knowledge, if not for their own mental satisfaction for sustaining contact with their fellows in examining.

To put an end to the public lies introduced into the various systems of government, and regulations, and practice of the apothecaries.

To deprive apothecaries of the power of prescribing medicines directly or indirectly.

To elevate practical chemistry and pharmacy to an independent profession, equal to, and on a level with, medicine.

To increase the dignity of the apothecaries by confiding to them half the responsibility of the National Pharmacopœia, and by preventing them from selling drugs, perfumery, tea, sugar, or chandlery; and, in fact, to confine their privileges to making up prescriptions, preparing the materials necessary for so doing, and analysing all suspicious substances for legal medicine.

To place the compounding of medicines, one of the most important parts of the healing art, under the direction of responsible and properly educated persons, and thus secure the public against the numerous errors committed by the carelessness of masters and the ignorance and indifference of apprentices.

To get rid of the unprofitable institution of apprentices, by which the public is ill served, life often endangered, the time of youth wasted, and the expectations of parents for the progress of their children perpetually blasted.

To replace apprentices by a properly licensed body of paid assistants.

To put an end to the sale of patent medicines and nostrums.

To prevent the sale of any medicine whatever without the regularly signed order of a medical man, and thus preclude the possibility of the serious consequences so constantly

arising to the public health, from the pernicious habit of self-quacking.

To secure, by severe laws for the neglect of it, the prosecution of all irregularities in this important part of the healing art, and of every species of pharmaceutical quackery.

To oblige the members, by properly directed visits to their shops, laboratories, and premises, to have in them all the preparations of the National Pharmacopœia and its Supplements, and those of a good quality.

To guard as much as possible against accidents from poisoning, by strict laws regarding their sale, and severe punishments for the infringement of those laws.

To procure, for legal purposes, accurate analyses of every substance suspected to contain poisonous matter, and thus to prevent the public health being undermined, and, at the same time, defend individuals from false suspicion of poisoning.

To provide for the greatest possible advance in pharmacy, by constituting it the duty of one part of the body to analyse all newly proposed remedies the moment they are made known.

To enhance the esteem of the arts of pharmacy and chemistry, by enforcing not only a good, without vexatious, system of preliminary education, but true and efficacious knowledge of all the collateral sciences, without which chemistry and pharmacy cannot be scientifically followed up.

To assure the country that those passed possess substantially the elements of their profession.

To abolish the false system of certificates.

To destroy the monopoly of lectureships.

To prevent examiners, unfit for the office, being elected or retained.

To protect the pupil from unfair questions, or captious treatment in the examination.

To secure by a fine for rejection, that no man shall present himself without a proper quantity of knowledge.

To stigmatise dishonourable and recreant conduct in the members.

To create a fund for the wants of the Society.

A.—The Society to consist of

1. All members of the Worshipful Company of Apothecaries of London, either not practising medicine, or willing to abandon that privilege, in order to remain members of this Society.

2. All members of the Dublin Apothecaries' Company.

3. All doctors of medicine of any of the Universities of Great Britain, and all surgeons willing to abandon their right of practising medicine or surgery, for the purpose of becoming members of this Association.

4. All persons of whatever nation, and however and wherever educated, who may pass successfully through the examinations required.

5. Persons arranged into three classes; assistants, members, and examiners.

6. Persons commencing with the ~~students~~,

236 *Plan of an Universal Association of Apothecaries in Great Britain.*

libraries, property; and buildings of the Worshipful Company of Apothecaries of London, and of the Apothecaries' Company of Dublin, become common property of the Association, as a fund.

I must here remark, that, in my first series of propositions regarding medical men, in the 83rd No., vol. iv., of the London Medical and Surgical Journal, the property of the Apothecaries' Company of London is proposed to be allotted to the medical men, or doctors, and hence the article 6 of section A of those propositions must now be read:

6. The museums, libraries, property, and buildings of the medical part of all these bodies, save of the Worshipful Company of Apothecaries of London, to become common property.

7. Forty-one examiners, under 60 years of age, to be elected by a simple majority of all the members in each of the three countries,—England, Ireland, and Scotland, in order to commence the operations of the Society.

8. Eleven examiners to be chosen by simple majority of the examiners in the metropolis of each of the three countries, as the first annual councils.

The council to choose such known professors, or lecturers, as they may deem necessary to aid the examiners, until the Society have members sufficiently capable of examining in all the subjects, and to pay them for their labours out of the funds of the Society.

9. A president to be chosen by simple majority of each council for each of the countries for the first year.

B.—*Assistants,*

1. Chosen by the majority out of five examiners.

2. Equal in all their rights and privileges.

3. Cease to be so, even when chosen, on the examination being found to be unfair.

4. Eligible two years after they have served as assistants during two years, though they have not yet passed their twentieth year, to the rank of members.

5. Yield in all questions of conduct to a simple majority of the council of the country.

6. Must be paid for their services.

7. Pay to the general fund an annual subscription of five shillings.

8. Expelled *ipso facto*, upon conviction before any public tribunal of perjury, or of any other crime, or of selling any medicines without the order of a medical man, regularly signed and dated.

9. Alone permitted, in the absence of the principal, to make up the prescriptions and take care of his business.

10. Prevented making any preparations formed from poisonous substances, or themselves poisonous, without the superintendence of the principal, under pain of expulsion from the Society.

11. Required to observe the same regulations as the masters, with regard to the making up, sending out, copying, and preserving of prescriptions, under pain, for the first fault, of losing their title of assistant for the space of six months, for the second fault for the space of one year, for the third of being expelled from the Society.

12. Prevented, under pain of expulsion, quitting the premises of their employer during his absence.

C.—*Assistantship, Candidates for,*

1. Upwards of sixteen years of age.

2. Furnish no testimonials of study or acquirement.

3. Give notice to some one examiner, whether of their own country or not, of their intention to submit themselves for examination one month previously to the day on which they wish to be examined.

4. Deposit in the hands of the examiner, to whom they apply, previously to drawing out from the urn the names of the other four examiners, the sum of ten pounds.

5. Receive from the examiner a receipt for the money deposited.

6. Draw from an urn, into which the examiner has placed the names of all the examiners in the county in which he, the examiner, resides, the names of four examiners to complete the examining committee.

7. Retouch one-half of the sum deposited, in the event only of their successfully passing their examination.

8. Forfeit the sum deposited if they do not present themselves on the appointed day for examination.

9. Obligated to answer no questions except on the established points of those parts of the sciences and arts required in the next regulation.

10. Examined in—

Latin—Celsus, two first books.

Greek—Herodotus, two first books.

English—Grammar.

Logic—Whateley's.

Geometry—First four books of Euclid.

Algebra—First part of, with arithmetic.

Philosophy—Locke on the Human Understanding.

Botany—Elements of physiological and descriptive.

Mineralogy—Elements of.

Crystallography—First elements of.

Chemistry—Elements of.

Zoology—Elements of.

Pharmacy—Elements of.

Pharmacopæia—A perfect knowledge of the National Pharmacopæia and its Supplements.

Some one system of the elements of these sciences selected by the London Council.

11. Prohibited from occupying any situation as apothecary to public institutions, as dispensaries, hospitals, workhouses, and other public charities.

D.—Members,

1. Chosen by the majority out of five examiners.
2. Equal in all their rights and privileges.
3. Decide all questions of government by secret ballot.
4. Yield to the decisions in all cases of a simple majority.
5. Cease to be members, even when chosen, on the examination being found to be unfair.
6. Eligible to the office of examiners after twenty-five years of age.
7. Expelled, *ipso facto*, upon conviction before any public tribunal of perjury, or of any other crime.
8. Pay to the general fund an annual subscription of ten shillings.
9. Prohibited practising medicine directly or indirectly.
10. Make no agreements with medical men for the interchange of patients and customers, under pain of expulsion.
11. Confine themselves to preparing the preparations necessary for the study of chemistry, and for the prescriptions of medical men, to making up these prescriptions, and to the sale of the articles mentioned in No. 12.
12. Permitted to have in their shops, and to sell, all substances and apparatus necessary for the study of mineralogy, geology, natural history, crystallography, and pharmacy, to any one who may produce an order from a medical man, or a ticket bearing his own name, and showing that he has entered to some known lecturer, save in the cases of poisonous substances, which must be subject to the general law upon these substances.
13. Required, under a five pound penalty for each omission, to have in their shops all the substances, simple and compound, of which an indication or description is to be found in the National Pharmacopœia and its Supplements.
14. Have but one shop and set of attached premises for their art, so that, under pain of forfeiture of the contents of any others, their warehouse, and shop, and laboratories must all be on the same premises.
15. Permitted, besides keeping an open shop, exclusively to fill the places of apothecary to all public institutions, as dispensaries, hospitals, poor-houses, and other charitable institutions.
16. Employ as assistants none but persons received under the conditions specified in the law, and paid for their services.
17. Take no apprentices, under pain of expulsion.
18. Inform the council, under a fine of fifty pounds for neglect, of all infringements of the laws made by their assistants.
19. Absent themselves on no occasion, under a fine of ten pounds, from their premises, without leaving them in charge of a member of the society, or of a licensed assistant.
20. Entrust the functions of their business to no one but a member of the society or a licensed assistant, under pain of expulsion.
21. Open their door at all hours, and under all circumstances, under a fine of five pounds for each refusal, for the making up of prescriptions.
22. Have in their possession, and produce, whenever called upon by a medical man to do so, under a penalty of ten pounds for each refusal, a copy of the last edition of the National Pharmacopœia, and all its Supplements.
23. Submit, under pain of expulsion, to their shops, prescription books, or files, laboratories, and warehouses being examined, as often and whenever, and at whatever hour, by a committee of any five examiners appointed by the council, and bearing with it a written order to that effect, signed by the president.
24. Make use of the weights and measures alone chosen by the council, and indicated in the pharmacopœias, under pain of expulsion.
25. Retain and file, or paste into a book kept for that purpose, all prescriptions they shall have made up, and display them whenever called upon by the coroner, by the medical man signing them, or by the visiting committee of examiners, furnished with a written order from the council, and signed by the president, under pain of expulsion.
26. Return, under a fine of five pounds for every omission, an exact copy of every prescription sent to them for preparation.
27. Make up no prescription whatever which is not signed by the name and christian name of a medical man, and dated; and in which the names of the articles are, not with the directions, written in full, in Latin or in English, and the weights or quantities indicated by the symbols prescribed in the National Pharmacopœia or its Supplements.
28. Sell no poisonous substance, whatever may be the excuse of the demander, without an order, written, signed, and dated in full, by a medical man, under pain of expulsion.
29. Accompany, under pain of expulsion, with a clearly written indication of the necessity of caution, in following strictly the directions prescribed by the medical man, for fear of the consequences, every composition containing a poisonous substance.
30. Put up all articles having different directions, when more than one is sent for the same patient, in papers, boxes, or bottles of a different colour for each of the articles.
31. Write the labels invariably on paper of the same colour, or of a shade of the same colour as that of the paper, box, or bottle containing the articles, and have every label furnished with the written or printed name of the proprietor of the shop from which it is sent.

E.—Candidates for Membership.

1. Aged upwards of twenty years.
2. Furnish no testimonials of study or acquirements.
3. Give notice to some one examiner, whether of their own county or not, of their intention to submit themselves to examination one month previously to the day on which they wish to be examined.
4. Deposit in the hands of the examiner, to whom they apply previously to drawing out from the urn the names of the other four examiners, the sum of forty pounds if they have not been received assistants, and in that case of thirty pounds.
5. Receive from the examiner a receipt for the same.
6. Draw from an urn, into which the examiner applied to has placed the names of all the examiners in the county in which he, the examiner, resides, the names of four examiners to complete the examining committee.
7. Retouch one-half of the sum deposited in the event only of their successfully passing their examination.
8. Forfeit the sum deposited if they do not present themselves on the appointed day for examination.
9. Obligated to answer no questions except upon the established points of the sciences and arts, indicated in the next regulation.
10. Examined in—
Latin—Cicero de Oratore et Celsus.
Greek—Herodotus and Dioscorides.
French—Elements of.
English Composition—On a chemical or pharmaceutical subject, drawn from an urn, into which each of the five examiners has deposited one in a sealed envelope, by the candidate himself.
Logic—Whateley's.
Philosophy—Locke on the Human Understanding.
Natural Philosophy—Elements of.
Geometry—First six books of Euclid.
Algebra—First parts of.
Arithmetic—Generally.
Trigonometry—Plain.
Crystallography—Elements of, as Brooke's
Mineralogy—Elements of, and those substances employed in chemistry.
Botany—Elements of physiological, descriptive, and medical.
Chemistry—Analytical and synthetical generally.
Pharmacy—In its most extended sense.
Pharmacopœia—The National, and its Supplements. Knowledge of all the substances, simple and compound, with their natural history and properties, simple and relative.
Legal Medicine, with Toxicology—Those parts which refer to the composition and sale of medicines, and the tests and analysis of matters suspected to contain poisonous substances.

F.—Examiners.

1. Unlimited in number.
2. Chosen from members by the majority out of five examiners.
3. Have no privilege over the members, save that of being eligible for the council, that of being employed in the analysis of matters suspected to be poisonous, and that of belonging to the visiting committee.
4. Cease their functions after 60 years of age.
5. Degraded to members upon being convicted by any one of the councils of refusing, except in case of illness, to examine, or to analyse for legal purposes, or to visit, and of partial or unfair conduct in the examinations.
6. Paid for their journeys, analysis for legal purposes, visits, and loss of time, by the body in general.
7. Meet for examination in an apartment open to all the members of the profession.
8. Assemble for examination in the chief town of the county to which they belong.
9. Are special or general; special for one or more sciences, general for the whole of them.
10. Examine whenever called upon, three weeks' previous notice having been given them.
11. Five in number for each examination.
12. Three of the five for the examining committee always general examiners.
13. Place the names, whenever applied to individually, for examination, of all the examiners in the county in which they reside, each in a sealed packet, into an urn, and allow the candidate to draw out four to complete the examining committee.
14. Susceptible of being refused, to the number of three, after the first drawing by the candidate.
15. When refused by the candidate, replaced by a second drawing by himself from the same urn, the names of the refused examiners having been replaced in the urn.
16. Advertise the four examiners so chosen of the time, place, and object of their re-union.
17. Refuse examination in the county, if there be not a sufficient number of examiners to constitute a committee.
18. Choose in the committee for examination, one of their number for a presiding examiner to direct the examinations, and defend the person examined from vexatious and unfair treatment.
19. Observe the same rules, except with regard to the amount of the deposits, and the subjects of the examinations with the candidates for the assistantship, the membership, and the examinership.
20. Demand from all candidates, previously to their drawing, the complements of the examining committee from the urn, a deposit of 10*l.* for the assistantship, of 40*l.* for the membership, and of 20*l.* pounds for the examinership.

ship, and in the event of their success, return to them immediately one half of the amount.

21. Put questions to the candidates for the assistantship, only on the facts of the elementary parts of the sciences and arts indicated; for the membership, only on the facts of the elementary branches when indicated, and on those of the sciences or arts generally, when required in the regulation; for the examinership, on every department of the various sciences and arts required from the member, or on any other subjects connected with the profession for a general examinership; and the same on the special science, or sciences, for a special examinership.

22. Conduct the examinations on Latin, Greek, French, English composition, both *virâ voce*, and by a series of written questions, to be answered in writing; the examinations in logic, philosophy, natural philosophy, geometry, algebra, arithmetic, and trigonometry, by written questions, to be answered in writing only; and all the remainder of the examinations *virâ voce*.

23. Conduct the examinations on crystallography and mineralogy by questions on parts of the subjects required for each examination, and upon specimens submitted to the observation of those examined.

24. Conduct the examinations on botany by questions on the elements of physiological, descriptive, and medical botany, and by causing the candidate to recognise at sight, or by examination with the aid of a general system, the plants of the National Pharmacopœia and its Supplements.

25. Conduct the examinations on chemistry, pharmacy, and the pharmacopœia by questions on the principles and practice of these subjects, and by requiring such compositions or decompositions of substances, chiefly connected with the pharmacopœia, and such manipulations, chemical and pharmaceutical, as may be judged necessary by the examiners, within the limits of the extent of knowledge required for each class of persons examined, the materials and instruments being furnished to those persons.

26. Conduct the examinations in legal medicine with the greatest care, requiring such analysis of artificial compositions containing poisons, as may be deemed necessary by them, and written details of these experiments, such as are requisite for the coroner, or a court of justice, and verbal answers to such questions and doubts as might arise from these descriptions.

27. Decide, by a simple majority, the acceptance or rejection of the candidate.

28. Return to the successful candidate half of the money deposited by him previously to his examination, immediately after its conclusion.

29. Transmit the funds received, with a written account of the result of the examination, to the metropolitan council of the country in which the examination takes place.

Examiners employed in the Visiting Committee.

30. Five in number for each visiting committee.

31. Selected for the visiting committee from the examiners of the county in which they are to visit, and in the event of there not being enough in the county, from those of the largest adjacent county.

32. Remain visitors during one year.

33. Elected as visitors on the 1st of January of each year by the president for the year in council, immediately after his election, drawing out from an urn, into which the names of the examiners in each county have been placed in sealed packets, the names of five.

34. Meet for visiting at the places and times appointed by the metropolitan councils, under pain of forfeiture of their titles of examiners.

35. Give no notice of the time or hour of their visits.

36. Visit at no fixed hours.

37. Choose previously to each visit, by simple majority, one of themselves to preside, direct the order of the proceedings, and draw up and transmit the report.

38. In visiting, present an order of the metropolitan council, signed by the president thereof, as the evidence of their authority.

39. Decide, when visiting, all questions of doubt by a simple majority.

40. Take reports of their visits, and transmit them forthwith to the metropolitan council.

41. Sign individually the report of each visit before its being sent to the metropolitan council.

42. Examine at the visit the shop, warehouse, laboratory, and premises, connected with the business of the person visited, so as to ascertain the existence therein of all the simple and compound substances contained in the National Pharmacopœia and its Supplements, of the National Pharmacopœia itself, with its Supplements, and of the weights and measures required; the accuracy of the arrangement of the prescription book or file, and the purity and goodness of the preparations, and the fulfilment of all the regulations relating to the premises of an apothecary.

Examiners employed in the Chemico-Legal Committees.

43. Five in number for each chemico-legal committee.

44. Elected upon the chemico-legal committee by the coroner's placing in the presence of the jury into an urn all the names of the examiners in the county in which the accident happens, in sealed packets, and drawing out five to form the committee.

45. Wait upon the coroner, whenever furnished with a summons signed by himself and a jury, under a penalty of 50*l.* for the first, and expulsion from the society for the second refusal.

46. Receive from the hands of the coroner

240 *Plan of an Universal Association of Apothecaries in Great Britain.*

alone all matters to be analysed for judicial purposes.

47. Proceed, upon having received a substance or substances from the coroner for analysis, forthwith, and with the shortest possible delay, to the analysis, in presence of any one or more of the members or assistants who may desire to be present.

48. Choose, when called upon a chemico-legal committee, from among themselves, by simple majority, a president to detail and draw up three similar written reports, to be signed by the whole of them, of the experiments and results of the analysis, one for the coroner, one for their own president, and one for the metropolitan council.

49. Present the report of the experiments and results of their analysis to the coroner, through the president.

50. Deposit the results or material proofs of their analysis, as far as possible, in the hands of their president, to be laid by him before the coroner, and subsequently, if required, before the necessary tribunal; and lastly, to be transmitted by him to the president of the metropolitan council, with a view to their being preserved in the museum of the Association.

51. Forfeit for ever the title and rank of examiners, upon a breach of any one of the laws for which the punishment is not already indicated.

G.—Examinership, Candidates for,

1. Have at least twenty-five years of age.

2. Give notice to some one examiner of their intention to submit themselves for examination, one month previously to the day on which they wish to be examined.

3. Produce to the examiner to whom the notification is made, their certificate of age and of membership.

4. Deposit in the hands of the examiner to whom they apply, the sum of 20*l.*, previously to drawing out from the urn the names of the four examiners, to form the complement of the examining committee.

5. Receive from the examiner the receipt for the money deposited.

6. Draw, after having made the deposit, from an urn, into which the examiner has placed the names of all the examiners in the county in which he, the examiner, resides, the names of four examiners, to complete the examining committee.

7. Retouch the half of the sum deposited in the event of their successfully passing their examinations.

8. Forfeit the sum deposited if they do not present themselves on the day appointed for examination.

9. Answer any questions, theoretical, practical, or positive, that may be put to them for the sciences in which they demand examination, if for specific examiners; in all the sciences and arts required from the candidates for the membership, if for general examiners.

H.—Councillors.

1. Eleven in number for the metropolitan towns of each of the three kingdoms.

2. Chosen by a simple majority of the examiners resident in the metropolis of each kingdom.

3. Elected by ballot and simple majority on the 1st of January for each year.

4. Announce the day of election of the new council, one month previously, in the public journals.

5. Choose, on the day of, and immediately after, their election, by simple majority, one of their own body as president for the year.

6. Present to the president, immediately after his election, an urn containing successively the names of the examiners of each county, in sealed packets, in order that the names of five may be drawn by him to constitute the visiting committee for the year for each county, and, in the event of there not being sufficient examiners in any county, an urn containing the names of the examiners of the largest adjacent county for the same purpose.

7. Appoint the time of meeting and of visiting of the visiting committees.

8. Forward to the examiners an announcement of their election to the visiting committees, signed, and orders signed by the whole of them, and countersigned by the president as the authority for the visits.

9. Are honorary officers, and consequently unpaid for their services.

10. Degraded, *ipso facto*, by a refusal or neglect to perform any of their functions to the rank of member.

11. Vote on all questions laid before them in council.

12. Meet once a month for the despatch of regular business.

13. Meet also for the purpose of deliberation whenever there is any difference of opinion on points of government.

14. Assemble in an apartment open to all the members of the profession.

15. Confer, in re-union of the three kingdoms, and by simple majority, with the government, on all subjects connected with the profession.

16. Change none of the principles of the Association without consulting and receiving the assent in writing of a simple majority of the members.

17. Of Dublin and Edinburgh subservient on all other matters, but those mentioned in No. 15, to those of London.

18. Annul the election of a member, or of an examiner, or of an assistant, or other officer, on proof being laid before them of the elections having been unfairly neglected.

19. Take cognisance of the conduct of the assistants and members, and inquire into all accusations against them connected with the laws of the society.

20. Analyse all new substances proposed as

remedies, when chosen by lot on an analysing committee.

21. Five in number for each analysing committee.

Councillors on the Analysing Committees

22. Chosen by the president drawing from an urn, into which the names of the eleven councillors of the country in which the discovery is first made known, placed in sealed envelopes, the names of five to constitute the committee.

23. Elect one of their number by simple majority as president of the committee, to take down notes of the experiments, and draw up a report on their results.

24. Present the reports of their labours to president of the council, through their president.

25. Preserve specimens of the substances analysed, and of the products of the analysis, in the museum of the body.

26. When chosen, proceed forthwith to the analysis with the least possible delay.

Councillors

27. Conduct, and are responsible for, the affairs of the society.

28. Determine the amount of fees to be paid to the examiners for the examinations, and to the visitors for the visits.

29. Frame and sustain to a level of the science, with the councillors of the medical body, a National Pharmacopœia for the United Kingdoms, in which their duty shall be the chemical and pharmaceutical parts of the subject, with a history of the combinations and decompositions.

30. Publish, in concert with the councils of the medical body, at the close of each year, such additions and corrections of the National Pharmacopœia, under the form of supplements, as shall be deemed necessary by the councillors of the two bodies, until a general vote of the members of both bodies shall call for a new Pharmacopœia.

31. Select the books, systems, and elements of languages, sciences, and arts, in each of the branches of study required, in which the examinations are to take place.

32. Take care of the museums and libraries, seeing that they are properly lighted, cleaned, and supplied.

33. Remove all obstacles to the studies of the members, and of young men studying the profession.

I.—President of the Association

1. An honorary officer.

2. Elected on the 1st of January every year.

3. Chosen from the council by a simple majority of its new members for each of the three kingdoms.

4. During the last year presides at the election of the new council and president, without voting on the last, and then vacates office.

VOL. V.

5. Of London is the depository of the funds finally, of each country temporarily.

6. Of each country disburses the funds under the approval of the council.

7. Of each country signs all obligations of the society.

8. Calls all meetings of the council.

9. Prosecutes, in the name of the society, all persons exercising the arts of chemistry and pharmacy without the license of the society, and all persons vending nostrums and patent medicines.

10. Decides all questions of order in the meetings of the council.

11. Is judged in all cases of accusation of want of fulfilment of his duties by the remainder of the council, aided by the oldest on the list of examiners.

12. Is degraded to the rank of member whenever pronounced guilty by a majority of his judges of any breach of duty.

TRANSLATION OF M. ALIBERT ON THE DISEASES OF THE SKIN.

BY SAMUEL PLUMBE, M.R.C.S.

Late Senior Surgeon to the Royal Infirmary for Children, &c.

Dermatoses Eczemateuses.—SPECIES IV.

Zoster.—English, Shingles.—Zoster manifests itself by an eruption of vesicles clustered together, and surrounded by a red inflamed areola, taking the figure and course of a belt suspended on the body, and extending from the linea alba towards the spine or across the shoulders, and sometimes surrounding the neck like a collar. It is preceded and accompanied by sensations of burning, itching, &c. After a time the vesicles disappear, dry up, and leave the skin, where they have formed, of a red colour, which gradually disappears. It is supposed by many to be analogous to pemphix, but without sufficient ground.

For the convenience of description, we divide them into the acute and chronic forms.

The acute is most commonly seen. It attacks young persons and those adults who enjoy robust health. It appears most frequently on the right side of the body, though the left is occasionally attacked by it.

The chronic form has been pronounced never to have existence by persons unqualified to pronounce an opinion. There certainly have been cases where it has existed months and even years.

Authors are not agreed as to the place which zoster should occupy in nosological arrange-

ment. Some have classed it with erysipelas, others as a form of herpes; but it is evident that no great likeness exists on either side. It is a distinct disease, but most resembles pemphix; and so far as regards the contents of the vesicles, there is almost an absolute identity. This disease is seated in the papillæ of the cutaneous surface, which explains the frightful torments the patients are condemned to*.

The active form of zoster is not uncommon; it is often seen in the hospitals of Paris, and has received a multitude of names. It occupies generally only one side of the body, most frequently the right, from which it extends towards the navel and spine. I believe it never entirely surrounds the body; but I have seen it wearing the form of two horse shoes, one before, the other behind, the extremities of which did not very closely approach. Some have described it in the form of a ribbon, extending down the fore-arm and arm, and now and then it surrounds the neck. The duration of the active form is from two to three weeks. The size of the vesicles, which, as has been observed, are always surrounded by a red areola at the commencement, are not larger than lentil seeds, and begin to increase in size. At this period the patients experience severe pains in different parts of the body of a lancinating and pricking nature, which are intolerably severe, and which increase as long as the eruption continues to spread, and as the vesicles become united to each other, and form a large erythematous band.

We cannot describe this disease without noticing the suffering accompanying its development; this consists of sharp and burning and itching pains, sometimes constant, sometimes only of several hours' continuation. The patient feels as if he were surrounded by a belt of fire, or expresses himself as if seized by the claws of a burning instrument. It is like the vulture consuming the entrails of Prometheus, said Darwin; and Tulpins, evi-

dently aware of the precordial pains, called it herpes precordia exedens. No relief is felt, except by the use of cold applications.

Chronic Zoster.

The form above-mentioned goes through the course described, and terminates; but the chronic evinces successive crops of eruptions of vesicular formation, accompanied by the same pains as belong to the acute. Patients often leave St. Louis apparently cured, but speedily return with the disease again upon them. In some cases fissures containing bloody matter are seen. What is most discouraging in this form is, that the internal pains remain, and are severe, though the external disease has disappeared. I have seen cases where great itching of the skin, or deep-seated pains, remained a long time after the eruption had disappeared; and, in one instance, it seemed likely to continue for life, having set in at the termination of menstruation.

There is no reason to repeat that the phlyctenæ of zoster are always of small dimensions, when compared to the bullæ of common pemphix; they may be said to be no larger than a common pearl. They contain a small drop of limpid fluid, either transparent, or of a yellow colour. The pellicle containing it withers, becomes wrinkled, and separating, leaves the cutis denuded. When several vesicles join together and become broken, the edges of the spot, after a certain time, are of a deep red or scarlet colour, the middle being of a faded grey colour. The sero-purulent discharge which flows from all parts of the abraded surface accumulates in some parts, and resembles gum-drops. Febrile symptoms do not belong to this form, and occur in conjunction with it only now and then accidentally.

Etiology.

Bilious disorders, a scorbutic diathesis, depraved humours, have been placed among the assigned causes of different authors. I have myself observed it consequent on hysteria, and in patients suffering from suppressed hemorrhoidal or menstrual discharge; anything impeding perspiration may also produce it. Violent affections of the mind, followed by severe pains in certain parts of the body, lead to the eruption in some cases.

* Rayer flatly denies the existence of much pain or suffering. "Jamais elles ne produisent les douleurs atroces dont unpathologiste moderne a parlé."—page 204. A moment's consideration of the structure of the cutis will disclose the truth.

Treatment.

The treatment of zoster requires much care and methodical attention. Those who consider it of little importance, have not carefully attended to it. In infancy and youth it is sufficiently mild, but sometimes when attacking old people it is of murderous fatality. We noticed the case of a man in the Hospital of Incurables, who expired under the most frightful sufferings. It is unsafe to attempt the cure of these affections, if any suspicion be entertained of the existence of organic disease. Periodical headach has been cured by its appearance, even where epilepsy was feared from the violence of the former.

Abstraction of blood from the arm, or from the neighbourhood of the part by leeches, are of common use. Oleaginous and milky fluids for bathing the parts, as also decoctions of mallow or linseed, are advantageous, and particularly necessary when a tendency to ulceration or irritation manifests itself, and there is a black or sanious discharge. Pommades of henbane and belladonna and of opium are employed with benefit, and if the skin becomes gangrenous, local antiseptics should not be neglected.

The allaying of pain is the grand difficulty which we meet with in this disease, as usually seen. The external employment of nitrate of silver, "la méthode ectrotique" of M. Lenes, as published by him, I have entertained a high opinion of for some time, and M. Lisfranc has shown to his pupils several cases of individuals who rejoiced at having submitted to it. The suffering is, of course, acute at the moment of its application, but it soon ceases, and the morbid irritation is singularly reduced. Other authors have sought to bring about the same results by blisters. Cold applications and bathing in the current of rivers gives relief. A mild regimen is also necessary, and anything likely to produce gastric irritation is carefully to be avoided. Ordinarily advise a solution of the neutral salts in butter-milk, chicken or frog broth; mild narcotic medicines may be used to procure rest.

It is a curious fact that the disease occurring on the right side disappears far more speedily than when it appears on the left. I am quite unable to explain this. Is it because of the neighbourhood of the liver, and the

proneness of this organ to disorder, and the consequent disturbance of all the digestive organs? Future observers may be able to solve this question.

Foreign Medicine.

Maladie de Bright.

UNDER the influence of the humid state of the weather which was predominant during the last three months of 1833, M. Baudelocque, of the Hôpital des Enfants Malades, noticed a great number of cases of anasarca, of which some were idiopathic, others symptomatic; sometimes they were primitive, sometimes consecutive to the febrile exanthemata, and to scarlatina in particular. The pathological phenomena observed in these patients have been somewhat similar to those which occur in cattle feeding in damp pasturages. In no case has the general or partial œdema appeared to depend on lesion of the liver, or central organ of circulation. These alterations of structure have been equally rare in infants and adults. In three subjects, attacked with general dropsy, the presence of albumen in the urine was observed; two of these patients died, and, on examining the bodies, the alteration in the kidneys, mentioned by Bright, and which has recently been the subject of the researches of Drs. Christison and Gregory, of Edinburgh, was found. This disease has been exclusively observed in adults and old men, and it was supposed that infancy was exempt from its attacks; but the recent investigations of Wels, Blackall, and Hamilton have dispersed all doubts, and proved that this form of complaint may occur at almost any period of life. The cases which have fallen under the notice of M. Baudelocque also have confirmed these latter opinions. Amongst the foreign reports will be found one extracted from the Gazette Médicale, and illustrative of this point. — *Gazette Médicale.*

Extracts from the Life of Cuvier.

BY M. PARISET.

It was in the year 1788 that Cuvier went to reside at Fiquainville, in Normandy, where, although only 18 years of age, he had been appointed tutor to the son of a gentleman there living. His active mind immediately directed

itself to the investigation of the objects which the nature and situation of the place afforded, and which, from its propinquity to the sea, were not few. His attention was principally directed to the study of insects, fishes, and the moluscæ, of which last Aristotle has so happily sketched the history and anatomy, and of which class some enjoy nearly all the functions of fishes, without however having with them the least analogy; closely approximating and yet being widely separated from the class of vertebrated animals, both in their nature, the number of their organs, and the peculiar resemblances to each other, from which it happens that the pulp is constructed on a plan which we do not recognise in any other class of beings, and from which Cuvier already concluded against certain speculative ideas, that here, at least, nature had left a gap, a manifest void, which overthrew all the vain systems of the chain of beings. One particularity of these animals, and of Cuvier himself, was that they furnished him with the ink with which he wrote their history. This ink, comparable if not identical with Indian ink, is a black liquid, conrescible, soluble, and indelible, and served to transmit to paper the preparations of the animals themselves, made by his delicate scalpel. These designs, made by Cuvier with this ink, are now considered his masterpieces, and dispute the palm of boldness and neatness with the works of even the most celebrated artists. His studies on the insect tribe apprised him that these animals, deprived of circulation, respired in a similar manner to plants, and were nourished by imbibition, as the zoophytes. In the neighbourhood of Caen there lived a citizen, a great amateur in natural history, who possessed a magnificent collection of fishes, principally from the Mediterranean. Cuvier became acquainted with this gentleman, flew to his treasure, and after some few journeys, by dint of his crayon, that precious instrument of observation and of memory, became in his turn their possessor, for, in natural history, the faithful representation of an object is the object itself.

(To be continued.)

Researches upon Croup.

Authors, who have written upon the affections of the larynx, have noticed the signal influence of a humid temperature upon the

development of diseases of this nature. This observation, of which the truth cannot be doubted, has been confirmed by the cases which have occurred in Paris in the last months. During December and January the temperature never ceased to be warm and moist, the thermometer being often 10 or 12 degrees above Zero; at these periods affections of the larynx and pharynx were very predominant; there were also a great number of catarrhal affections, and cases of angina, in which false membranes were found; and, in addition to these, there were observed several cases of true croup. This disease, become very rare during the last few years, has lately proved fatal to several patients at the Hôpital des Enfants: there have been three cases, all of which terminated in death shortly after their admission, and in all of which false membranes were found in the larynx, trachea, and bronchial passages. Tracheotomy was performed on one sufferer by M. Sanson, but we do not know the result. The disease has been equally prevalent with adults; M. Broussais, in one of his lectures on pathology, exhibited the larynx, the trachea, and the bronchi of a young soldier, who died at Val-de-Grâce with all the symptoms of croup, and in whose body the characteristic alterations of disease were observed.

Local treatment is alone efficacious in this complaint. Thus, when the false membranes have approached near to the arch of the palate, the amygdalæ, or the pharynx, which alone are accessible to these therapeutical plans of treatment, caustics, more or less irritating, applied to the false membranes, have destroyed their organisation, and effected a cure in them: when, however, these membranes are developed in the larynx, trachea, and particularly in the bronchi, the disease has proved beyond the resources of art, and all the patients who have been so attacked have perished. Professor Broussais has stated, in his lectures, that this affection is nothing more or less than an intense degree of laryngitis, and might be overcome by energetic antiphlogistic treatment. In the different autopsies, at which we have assisted, the mucous membranes of the air-tubes were pale, colourless beneath the false membranes, and in no cases, which have fallen under our notice, have we observed any sign of intense phlegmasia. Thus, a slight cough and hoarseness, without any appearance of ge-

neral re-action, marks the commencement of the affection in the larynx, which, all at once, and without any appreciable cause, becomes the seat of the membranous exudation. When the disease is declared, the antiphlogistic treatment has always appeared to us powerless. Every circumstance, indeed, causes us to doubt the inflammatory nature of this affection. If, therefore, it is to be called a phlegmasia, we must admit that its characteristics are peculiar, and differ from those of inflammations in general.—*Gazette Médicale.*

DR. COPLAND in the Chair.

Claims of Dr. Jones and Dr. Veitch to the Invention of the small Silk Ligature.—Metastasis of Gonorrhœal Discharge.—Sympathy between Disease of the Cardiac Orifice of the Stomach and the Heart.

THE draught of a petition to the House of Commons having been read and unanimously adopted by the Society,

Mr. Costello read some extracts from a letter sent to him from Dr. Veitch of Chelsea, claiming the priority of invention of the small silk ligature, an invention of which the merit has generally been ceded to Dr. Jones. Mr. Costello said, that what he had, at a former meeting, stated upon the subject, was merely historical, for he had not inquired particularly into the merits of the claimants of this important discovery. From what he had since heard, he should be inclined to consider as correct what Dr. Veitch had stated, and he was the more inclined to admit this, as he considered that such ready and willing conviction might act as an incentive to other and more worthy discoveries. Since the evening on which the subject of torsion of the arteries had been brought forward, he had received a communication from M. Amussat confirming the value of torsion, and alluding in particular to the case of Lord Nelson, in which the ligature did not come away for many weeks after its application, thus verifying the expression, that "the glories of Trafalgar hung upon a single thread."

Mr. Greenwood thought the very able manner in which Mr. Costello had brought forward the subject was in the highest degree praiseworthy; but still he could not agree with him as to the value of torsion, several cases being on record of secondary hæmorrhage occurring after such operation. With regard to Lord Nelson's case, he did not consider that it went far to support the argument for torsion. It was notorious that cases of amputation sometimes failed, but it would be absurd therefore to consider the operation as useless. After some further remarks on the subject, he concluded by remarking, that he felt certain the more the subject was inquired into, the more would the value of the ligature be estimated.

Mr. Costello explained the failure of an operation for torsion at the Hôpital Antoine by the want of tact which was displayed by the surgeon. In another instance of failure, only one side of the vessel was twisted; and again in a third unsuccessful case the forceps were not of the proper construction. Mr. Greenwood, in the course of his objections, had stated that Jones insists upon the complete division of the inner coat of arteries; now, if such was the fact, Jones argued in the most complete manner possible for torsion, since, in this operation, the inner coat was most perfectly divided. The immediate effect upon the inner tunic was one of the greatest advantage, for within an hour or two the plug is formed, whilst, in the operation by ligature, much longer time is necessary for the formation of an obstacle to the flow of blood.

Dr. Johnson remarked upon the merit which was undoubtedly due to Dr. Veitch for the invention of the silk ligature. The French had always been in the practice of applying some of lint or other foreign substance between the ligature and the coats of the arteries, fearing the division of the latter; and, until the time of Dr. Veitch, no person had applied the single ligature to the human subject, for the experiments of Jones were not performed on man, and were, on that account, not conclusive, as it is well known the effects of operations upon animals do not always resemble those upon human beings.

Dr. Ryan was gratified to hear Dr. Johnson coincide in the merits of Dr. Veitch's invention. That gentleman had applied the small ligature in the presence of Dr. Johnson and Dr. Ham-

mick, so far back as 1805, on the human subject, and mentioned his success to the surgeons of the Royal Infirmary, Edinburgh, soon afterwards, and long before Dr. Jones had performed the operation on animals, or his work had appeared.

Mr. Greenwood, in referring to the remark of Mr. Costello, that although Velpeau had displayed a want of tact in twisting the artery, still he had admitted the value of this mode of operating, said that it was a curious fact, that Dupuytren, who witnessed Amussat operate, and who lauded the operation, had never resorted to its use in the Hôtel Dieu, even during the stirring times of the Revolution in 1830.

Mr. Costello replied, that torsion was not known in 1830.

Some difference of opinion having arisen between Mr. Hunt and Mr. Greenwood as to the explanation of a passage in Jones, touching upon the division of the inner and middle coat, by applying the ligature in a perfectly circular manner,

Dr. Johnson rose and explained the discrepancy, by stating that a fine round ligature applied equally would perfectly divide the coats, whilst a larger one, by causing an inequality on one side, would not act in this way.

Dr. Copland referred to the rapidity and manner in which the exudation of lymph took place, and by means of which hæmorrhage was restrained.

Mr. Costello said, all those surgeons who had employed torsion had concurred in praising it, whilst the objections raised against it were made by gentlemen who had not tested its merits by experiments. He thought that if those persons who did object to it would turn their eyes to what was going forward on the Continent, and more particularly at Hamburg, they must feel convinced that great success had attended its introduction into practice.

Mr. Peregrine wished for the opinion of the Society on a case of acute gonorrhœa, in which the discharge was suddenly suppressed on the supervention of a catarrh, and an inflammatory and swollen state of the tonsils. By resorting to emetics, blisters, &c., this condition of the amygdalæ subsided, and was immediately followed by the renewal of the gonorrhœal discharge. He would not offer any

opinion on this case, but was desirous of knowing whether it might not with propriety be termed a case of metastasis.

Dr. Copland observed, that several cases similar to the preceding were on record.

Dr. Johnson had met with discharges, in children of very tender years, which could not by any possibility be considered as gonorrhœal in their nature, and which would entirely cease upon the use of remedies, and again make their appearance. He admitted, however, that it was not so common for specific diseases to stop in this sudden manner.

After some further observations on this subject by Mr. Hunt and Mr. Peregrine,

Dr. Johnson brought before the notice of the Society an instance of the sympathy between disease of the cardiac orifice of the stomach and affection of the heart. A gentleman had been ill for some years, with difficulty of deglutition, palpitation of the heart, emaciation, &c.; these symptoms were aggravated at intervals, and were considered by an eminent surgeon, who had failed in attempting to pass a bougie, to be caused by strictures in the œsophagus. The case terminated fatally last week, and proved, on examination, to be one of carcinomatous disease, situated at and extending round the termination of the œsophagus in the stomach. The heart and liver were perfectly healthy.

In answer to a question, Dr. Johnson said it was impossible, by means of the stethoscope, to discover, during such violent action of the heart, whether that organ was enlarged or not; it was only by attentively inquiring into the history of the case that it could be discovered.

Dr. Copland said he had observed that disease of the cardiac portion of the stomach was not unfrequently attended by this distressing palpitation of the heart.

MEDICAL SOCIETY OF LONDON.

Monday, March 17th, 1834.

W. KINGDON, Esq., President, in the Chair.

Diseases of Children—Ptyalism—Sympathy between Affections of the Thorax and Brain—Effects of Mercury on the System—Symptoms and Treatment of Water Canker.

Mr. ROBERTS entered into an explanation of

a case of salivation, occasioned by the use of mercury, to which he had alluded at the last meeting. At that time Dr. Whiting had stated that it was not of the nature which he (Mr. R.) had considered, but was an instance of the disease called gangrena oris. The symptoms, both local and general, were totally different from those of gangrena oris, as mentioned by Dr. Hamilton. In alluding to this distressing consequence of the use of mercury, he had not meant to detract from the value of that medicine, but merely to instance effects which sometimes followed its use.

Dr. Whiting said if the case had been mentioned on a former evening, as now, he certainly should not have considered it as one of gangrena oris; this latter disease, mentioned by Dr. Hamilton, was not so unfrequent as generally supposed. Many practitioners in London were in the custom of attributing it to the effects of mercury; it, however, frequently existed when no mercury had been given.

Mr. Headland stated, that in speaking of the use of calomel in thoracic disease, he had not for one moment considered it as alone sufficient for their cure, but in that peculiar form which he was disposed to consider as not of an inflammatory character, but depending upon irritability and sympathy with the brain, its value was undeniable. Notwithstanding what Dr. Whiting had said respecting the stethoscope, he still could not coincide with him as to its great value; for in such instances as those which he had mentioned, its application was unnecessary, and frequently fallacious.

Mr. Bryant perfectly agreed with Dr. Whiting in his opinion of the great utility of auscultation: frequently when the symptoms were obscure, the application of this instrument to the heart at once discovered the nature of the disease.

Mr. Dendy did not think that the diagnosis in the cases mentioned by Mr. Headland was so very difficult; one great point of discrimination was in the remission of the symptoms. The state of the pupil also threw much light upon the seat of the complaint; if contracted, it was reasonable to suppose that the head was most affected; in such cases much benefit was derived from the application of leeches behind the ears. In estimating the

value of calomel, it was necessary to bear in mind that it was not supposed to supersede the necessity for bleeding, which latter remedy seemed to possess the power of predisposing the body to a state favourable to the administration of other remedies.

Mr. Stevens had met with a form of disease not generally noticed by medical practitioners. It consisted of ulceration in the cheek, following the administration of calomel, and commencing in a small black spot, it rapidly increased in size, and was accompanied by a most intolerable fetid odour, which at once discovered the nature of the complaint. A case of this nature had been admitted at Guy's Hospital, and had been attributed to mercury, the parents of the child having said that it came on after the use of some white powders.

Dr. Whiting said the case mentioned by Mr. Stevens had been under his care previous to its admission into the hospital; therefore it was not caused by mercury, for only two grains of calomel had been given, joined with other purgatives, but was a true instance of water canker.

Mr. Hooper had met with two cases precisely resembling that seen by Mr. Stevens, and had he not seen the whole progress of the treatment, should certainly have attributed their origin to mercury. They were generally found to occur in some debilitated state of the constitution consequent upon scarlatina, measles, or some other complaint.

Mr. Bryant thought it possible that even two grains of calomel might be sufficient to produce all the symptoms related by Mr. Stevens in some subjects. In treating the diseases of children, it was necessary to bear in mind the tender state of the system and peculiarity of constitution; he thought the observations of Dr. Uwins, at the last meeting, with reference to the state of the nervous system in bronchitis, were particularly valuable and important.

Mr. Kingdon had seen the bad effects which sometimes resulted from the free use of mercury; these were, however, only exceptions to the general rule, and were to be attributed to some peculiarity of constitution.

Mr. Proctor noticed the absence of any affection of the tongue in these cases, as clearly marking the distinction between this disease and ptyalism; he could not concur in the

great dread which some surgeons had of blood-letting, for he had frequently applied leeches largely, and had seen much benefit result from their use.

Dr. Waller observed that in those children who died of thoracic disease, there was generally found effusion on the brain, attention therefore ought to be directed to both these organs; he trusted that what had been said respecting mercury, would not prejudice any gentlemen against the use of this remedy, for he considered it one of our most valuable medicines. In connexion with bleeding he was in the practice of using mustard poultices instead of blisters, which he had frequently found injurious.

Mr. Kingdon had found that the majority of these cases of ulceration of the face, if treated early, might be cured. He had found a medicine composed of Peruvian bark, rhubarb, ginger, and subcarbonate of soda, given in milk every three or four hours, particularly efficacious.

Mr. Dendy had seen the local application of balsam of Peru, and the use of muriatic acid and tartrate of iron of great value.

Dr. Whiting said that stimulants were recommended by Dr. Hamilton; when granulations could be produced, the probability of the patient's recovery was great. The application of the compound tincture of myrrh with equal parts of the diluted sulphuric acid of the Pharmacopoeia, applied at intervals of ten minutes, until smarting was occasioned, proved of the greatest service; one case which had not been seen until the disease had made some progress, terminated in permanent lock-jaw: this complaint appeared to be of a specific nature, and was very different from other kinds of sloughing; it corresponded in some of its characters with that form of disease caused by ergot of rye.

Mr. Dendy stated that Mr. Wood of Oldham had related some cases of a similar nature, in one of the earlier volumes of the Medico-Chirurgical Transactions.

Several other gentlemen took part in the discussion, and mentioned several interesting cases.

THE

London Medical & Surgical Journal

Saturday, March 22, 1834.

PARLIAMENTARY COMMITTEE—UNIVERSITIES—APOTHECARIES.

THE Parliamentary Committee commenced the operation of examining witnesses, rather unexpectedly, on Thursday the 13th instant, after our last number had gone to press. It was supposed that the examination would not have been entered upon for a few days later.

Of course we are not at liberty to reveal the tenor of the examination: but a fair opinion of its nature may be formed from the quality of the witnesses. The first person called was Dr. F. Hawkins, the Registrar of the College of Physicians; his official duties explain how it was that, on this occasion, he took precedence of the learned President. Were it not for some necessary explanation, touching documents in his custody, the Registrar would not, assuredly, have had the lead of the learned President upon such a momentous crisis, when the admirable tact and judgment almost intuitive, of the generalissimo,—all courtesy to the head of corporation delinquents apart,—might display themselves in governing the fortunes of the day.

Sir Henry Hallford has, however, since appeared. Up to a very late moment, even after the appointment of a Parliamentary Committee, the learned President had not given up all hopes of conducting the investigation, which he foresaw was inevitable, in his own way; at least he expected to have an inquiry of his own, in the shape of a Royal Commission. Whether this *ultimum moriens* is now at length defunct in the learned President's breast,—whether he still fosters this

“Hope against hope,”

is a problem upon the powers of illusion beyond our skill.

There will be found in another part of this number a copy of a paper sent by the Committee to the medical officers of Dispensaries, which will give the profession a foretaste of the inquiries into which the Committee is resolved to enter. Independently of the importance of the information which will be thus elicited in respect to Medical Reform, it will afford details of a very interesting nature for *the Statistical Society*, which has been just established.

We have had, upon various occasions lately, to animadvert upon the conduct of the Universities. The modifications in the course of medical study, requisite for a degree in medicine at Oxford, have been already commented on. We understand that, even now, changes of a like character are contemplated at Cambridge, of which the main principle is to shorten the period for obtaining a degree by one year, and to require two years' hospital attendance. It is surprising, indeed, that fool-hardiness can go so far as to intermeddle, *past* the eleventh hour, in such a matter. The only result that can be reckoned on, from such a proceeding, is probably the amendment of the returns already made to the Committee by the University. This new attempt, if our authority be correct, as well as the already celebrated innovation at Oxford, is doubtless the fruit of Sir Henry Hallford's visit to Alma Mater last year.

The same generous and distinguished men, whose useless efforts upon two late occasions to admit Dissenters to graduate at Cambridge, or at least to permit them to take medical degrees, we have had to notice, have again come forward with an appeal to Parliament for its interference. The notice of their petition, which is to be presented to the House of Lords by Earl Grey, astonished the Duke of Cum-

berland and that great Cambridge authority, Mr. Goulburn. Lord Althorp, in noticing this petition, took occasion to observe, that he saw no objection to throwing the Universities open to Dissenters.

These matters plainly indicate the feelings of the government, and leave no doubt that it is prepared to go along with the profession in despising the complaints of corporate prejudice and bigotry, which would, for selfish purposes, sacrifice the public interest. On a late occasion, too, the liberality of the government was manifested in a matter immediately concerning professional interests:—Upon the presentation, by Lord Durham, of the petition of the physicians against the college at Pall Mall East, Lord Lansdowne expressed his readiness to assist the petitioners; and there was some intimation of the appointment of a Committee of the Upper House, to investigate the whole subject; but we believe the inquiry is likely to be left altogether in the hands of the Committee of the House of Commons.

Such is the history of the movement towards medical reform up to the present date. It were, however, unjust not to notice the active co-operation the friends of reform have latterly received from *The Times*: the three most able articles it has published on this subject have done much to enlighten the public, and to assure it how deeply it is interested in the proper organisation of medical practitioners. We are happy to find the opinions advocated in this journal so much in accordance with those adopted in that influential quarter.

We have often deprecated the untoward influence which "the Hall, Bridge Street, Blackfriars," to use the expression of *The Times*, has by accident—rather let us say by culpable neglect—acquired over

the whole class of medical practitioners in this country. The history of that body from its establishment as a city corporation by James I. to the climax of its splendour in 1815, affords a singular instance of the fluctuations to which corporations calculated for other times are liable, when they have survived their original purpose, without the mending hand of the reformer*. The earliest event of importance occurred about the close of the seventeenth century, when the College of Physicians endeavoured to punish an apothecary for prescribing medicine gratis behind his counter, and then selling the medicine. This contest, in its day much celebrated in prose and verse, was carried to the House of Lords, where it was at length decided, that it was not unlawful for a vender of medicines to give gratuitous advice to those who came to buy from him. The true ground of that decision, so important in its consequences, is to be found in the narrow monopoly which the College of Physicians of that day had taken care to establish.

In the greater part of its subsequent history we find it for some time laudably engaged in pursuit of the profits of trade; in which, however, its eagerness to secure the supply of medicine to the army and navy, and several foreign companies, led it into various acts of a very dubious character.

About the year 1748, the Apothecaries' Company acquired a control over the venders of medicine in the neighbourhood of London; but, beyond the range of seven miles from the city, it was open to

every man that pleased to practice and dispense medicine.

Then came the celebrated act of 1815, by which the corporation was invested with a sovereign power over all the general practitioners of England. That act, it is well known, originated in a private meeting of some gentlemen who were interested in the duty on glass bottles. For some time, even the corporation itself took little interest in a measure which was to bestow upon it such unheard-of privileges; and at length, when it did exert itself, the Colleges of Physicians and of Surgeons refused to concur in an application to Parliament, to sanction a scheme for the education of general practitioners. It was the intention of the original projectors to crush altogether the dispensing trade of the druggist. The Bill expressly protected the rights of the druggists, as they then existed, from its operation. This plain departure from the original principle was, however, far outbalanced by the lucrative consequences of the remaining parts of this celebrated enactment; for it is expressly declared in the act, that the Society may appropriate the monies which it should receive by licences in any way they might deem expedient; in consequence whereof, the members of the Court of Examiners have pocketed, in the course of eight years before 1833, the net amount of 10,218*l.* 12*s.*! Soon after the passing of the Act, the Company turned all its attention towards enforcing its newly acquired legal rights, carefully abstaining, meantime, from interfering with such as wrote druggist over their door; and, we believe, a very large sum was spent amongst the lawyers of Westminster Hall, in punishing unfortunate delinquents. Within the last three years, finding it has secured by its term of apprenticeship a complete monopoly in general practice, it has cer-

* A tolerably correct history of the Apothecaries' Company may be extracted from the Introduction to Gray's Supplement to the Pharmacopœia, and the article Apothecaries in the Penny Magazine. We mention these books because they are in the reach of every reader.

tainly made some efforts to improve the professional education of the apprentice. How far short that education is of the qualification a practitioner ought to have, it is superfluous to say.

We apprehend it will be found impracticable, however desirable it may be, to separate completely the duties of the physician and the apothecary. We may for the present dispense with any discussion upon the bad effects of the union, as concerns the character and practice of the physician and the health of the patient. Still, with all the dangers of what our neighbours in France call *polypharmacie* staring us in the face, we suspect the pure apothecary could find bread nowhere except in large cities. We think, however, a partial remedy for the abuses arising from the union might be found by providing a proper tribunal for taxing an apothecary's bill for medicines. A power of this nature is possessed, or assumed, by the Apothecaries' Hall in Dublin. In conjunction with a measure of this kind, we would have it declared by act of parliament, if there is any doubt on the subject, that every medical practitioner, whether physician or surgeon, was by law entitled to a fair remuneration for his advice.

Every man, permitted to practise medicine, should be qualified to dispense it: whether he would provide his own drugs must be left to the discretion of each practitioner; but if he does furnish them, he should derive no profit from so doing, beyond the reasonable profit of a mere apothecary.

DASHING AUDACITY.

It is well known the President of the College of Physicians claims the right of introducing one Licentiate every year to the honour of the Fellowship. For the

last two years this privilege has not been exercised; and it is said, Sir Henry Hallford, M.D., &c., &c., &c., openly professes, as his reason for being so chary of his honours, that *there is not a Licentiate in London of sufficient talent and education to entitle him to the rank of a Fellow!* We wonder will the learned President venture to assign such a pretext before the Committee. Perhaps he has,—time will tell. There is nothing we are not prepared to expect from his “dashing audacity.”

Rebibsos.

Rules for the Restoration and Preservation of Health, and the Best Means for Invigorating and Prolonging Life. By GEORGE CHEYNE, M.D. 12mo. pp. 224. London: 1834. H. Renshaw.

Rules for Preserving the Health of the Aged, by means of Air, Clothing, Diet, Exercise, &c. By J. A. SALGUES, M.D. 12mo. pp. 307. London: 1834. H. Renshaw.

Born these works have been long patronised by the non-professional public. They contain a vast deal of good advice on the preservation of health, and the prevention of diseases. Those who follow the advice offered in them, will escape many diseases; and it is only to be regretted that the public are so little informed as to the means of preventing diseases. In both works there are prescriptions for treating diseases, but here we must observe, that the person who undertakes the cure of himself without a knowledge of medicine, has a fool for his patient.

The Monthly Archives of the Medical Sciences. Feb. 1834. Edited by Dr. HUNTER LANE.

This journal consists of original communications, reviews, and notices of books, abstracts from foreign and domestic medical literature, medical politics, and intelligence. The independent spirit of the editor entitles him to our respect, and his arrangement and selection of materials, display taste and judgment. We wish him success.

The Medical Quarterly Review. No. II.
Jan. 1834.

This new aspirant to favour consists of reviews, notices of books, original communications, collectanea, medical politics, and intelligence. The work is conducted with much spirit; the editor is a sharp critic, finding unpardonable faults with every author, great and small, and much fonder of strictures on the theory than on the practice of medicine. We offer this comment with good feeling, and if it be unkindly taken, we cannot help it. Time will prove whether the profession will think differently from ourselves.

On Dentition and some of the Incidental Disorders. By JOHN ASHBURNER, M.D.,
Lecturer on Midwifery, &c. Small 12mo.
pp. 234. London: 1834. Longman and Co.

This little volume contains a great deal of valuable information on a subject too much neglected by medical practitioners in general. The author adduces a host of evidence in proof of a position which no one experienced in the practice of medicine can doubt,—that the irritation of the nerves of the jaws may derange the whole functions of the body, and excite a crowd of functional disorders, which are generally ascribed to other causes. This unassuming production deserves the perusal and study of every one engaged in the practice of the healing art.

QUESTIONS

Which the Governors of Dispensaries are required to answer for the Information of the Committee appointed by the House of Commons to inquire into the State of Medical Practice and Education; and which the said Governors, having answered, are required to return, directed "To the Chairman of the Committee on Medical Education, House of Commons, London."

1. When was your dispensary first established?
2. How is it supported?
3. Are there in-patients as well as out-patients?
4. If so, what was the number of each in 1833? and what is the number of beds for in-patients?

5. State the number of medical, surgical, and midwifery cases in 1833.

6. What is the number of physicians, surgeons, apothecaries, nurses, and other officers attached to your dispensary?

7. What are the names of the physicians? Where did they graduate? When did they graduate? Of what medical or surgical colleges are they fellows, members, or licentiates? When were they elected officers of the dispensary?

8. What are the names of the surgeons? When did they graduate or obtain their diplomas? Of what medical or surgical colleges are they members, fellows, or licentiates? Are they members of any and of what company of apothecaries? Do they belong to the council or board of examiners, of any and of what college of surgeons? When were they elected officers of the dispensary?

9. Is the choice of your medical officers restricted to the graduates, fellows, members, or licentiates of any particular universities, colleges, companies, or corporations?

10. Would the holding of any particular religious belief operate to exclude a person from being one of your medical officers?

11. In whom rests the election of your medical and surgical officers? and what are the by-laws for regulating such elections?

12. What are the names of the house surgeons or apothecaries?

13. Do they actually reside at the dispensary?

14. How many times a week, and at what hours, are the other medical officers required to visit the dispensary?

15. In what manner and by whom are the medicines for the use of the dispensary supplied?

16. Is the person supplying the medicines a medical officer or governor of the dispensary?

17. What was the salary, and what were the emoluments, of each medical officer of the dispensary in 1833? and whence are the emoluments derived?

18. What was the rate of fees for a student's attendance on the medical and on the surgical practice of the dispensary in 1833? What was the amount of such fees, and the share paid to each medical officer in 1833?

19. Are any and what lectures given at the dispensary, and by whom? What is the

rate of fees for attendance on those lectures?

By whom are the lecturers appointed?

20. Are any of the lecturers also medical officers to the dispensary? and if so, what emoluments do they derive from those lectures?

21. By whom is the rate of fees for attending the medical practice of the dispensary, and for attending the lectures, regulated?

22. What was the number of pupils attending, 1st, the medical, 2nd, the surgical practice of the dispensary, in each of the years 1831, 1832, and 1833?

23. What was the number of pupils attending the lectures in the same years?

24. State, in detail, the income, the sources of income, and the charges upon income, the actual receipts and payments, and the balance in hand at the beginning and end of the year, for each of the years 1831, 1832, and 1833.

QUESTIONS

Which the Governors of Infirmaries are required to answer.*

1. When was your infirmary first established?

2. Does your infirmary depend for its support on endowment, on rates made for its maintenance, or on voluntary contribution?

3. How many beds are there at your infirmary for in-patients?

4. How many in-patients were admitted into your infirmary in each of the years 1831, 1832, and 1833?

5. How many in-patients were there at your infirmary on the 1st of January of each of the years 1832, 1833, and 1834?

6. How many in-patients, admitted into your infirmary in 1833, were, 1. medical cases, (a) acute; (b) chronic; and 2. surgical cases, (a) wounds and accidents; (b) chronic?

7. How many of the in-patients in your infirmary on the 1st of January, 1834, were, 1. medical cases, (a) acute; (b) chronic; and 2. surgical cases, (a) wounds and accidents; (b) chronic?

8. What number of capital operations was

performed at your infirmary during each of the four last years?

9. Class the number of capital operations performed at your infirmary during the four last years, according to their nature, and state the number belonging to each class.

10. What was the number of cases of fractured bone for which in-patients were admitted during each of the four last years, and what was the number of severe accidents?

11. Does your infirmary admit of out-patients? How many out-patients were visited in 1833; and how many were under visitation on the 1st of January, 1834?

12. How many of the out-patients visited in 1833 were medical, and how many were surgical cases?

13. How many of the out-patients under visitation on the 1st of January, 1834, were medical, and how many were surgical cases?

14. Are the out-patients visited at their own homes?

15. Are the out-patients visited by the medical officers of your infirmary, or by the pupils of the medical officers, or by whom?

16. What is the number of the physicians, surgeons, apothecaries, nurses, and other officers, attached to your infirmary?

17. How many of these are required to be resident, and how many are visiting medical or surgical officers?

18. What are the duties belonging to each of the aforesaid offices?

19. Do the resident or house physicians, surgeons, or apothecaries, of your infirmary actually reside, or do they live in the neighbouring town or city?

20. What are the names of the physicians? Where did each graduate? What are the dates of their degrees? Of what medical or surgical colleges are they fellows, members, or licentiates? When were they elected to the infirmary? In what capacity were they immediately before their election?

21. What are the names of the surgeons? Where did they graduate or obtain their diplomas? Of what medical or surgical colleges are they members, fellows, or licentiates? Are they members or licentiates of any and of what company of apothecaries? Do they belong to the council or board of examiners of any, and of what college of surgeons? When were they elected to the infirmary? In what

* This circular has also been addressed to the Governors of Hospitals, with the substitution of the word "Hospital" throughout for "Infirmary."

capacity were they immediately before their election?

22. Is the choice of physician, surgeon, or apothecary to your infirmary restricted to the graduates, members, fellows, or licentiates of any particular universities, colleges, companies, or corporations?

23. Is the physician, surgeon, or apothecary of your infirmary required to be of any particular religious persuasion, or would the holding of any particular religious belief be a ground for exclusion?

24. In whom rests the election of the medical and surgical officers of your infirmary; and what are the by-laws for regulating such elections?

25. State the name of the house-physician, house-surgeon, and house-apothecary, and the ordinary place of residence of each.

26. How many visits a week are required of the visiting physicians and visiting surgeons respectively; and what and how many hours are given to such visits?

27. In what manner and by whom are medicines supplied for the use of the hospital? What was the cost of medicines supplied to your infirmary in each of the years 1831, 1832, and 1833?

28. Is the person supplying medicines a medical officer or a governor of your infirmary?

29. What is the salary, and what are the emoluments of each officer of the infirmary, and whence are the emoluments derived?

30. What are the rates of fees paid by students for attendance on the medical or surgical practice of your infirmary?

31. To whom are those fees paid in the first instance?

32. Between whom are those fees divided, and in what proportions?

33. What was the amount of fees taken for attendance on the medical and surgical practice of the infirmary in each of the years 1831, 1832, and 1833?

34. What amount, derived from such fees, was paid to each officer in the infirmary, entitled to share the same, in each of the said years?

35. By whom is the rate of such fees regulated?

36. What was the number of pupils attending, first the medical, second the surgical,

practice of the infirmary, in each of the years 1831, 1832, and 1833?

37. What was the number of apprentices articulated to each medical officer of the infirmary in each of the said years?

38. Are apprentices to the medical officers of the infirmary required to pay the same fees for attendance on the medical practice of the infirmary that other students are required to pay?

39. Are members of the profession required to pay the same fees as students for attending the medical and surgical practice of the infirmary?

40. What are the regulations for admitting students or members of the profession to the medical and surgical practice of the infirmary?

41. By whom are such regulations made and approved?

42. By what universities, colleges, or companies, empowered to grant degrees, diplomas, or licenses to practise, is attendance on the practice of your infirmary recognised, as a qualification to be examined for such a degree, diploma, or license?

43. When was your infirmary first so recognised?

44. What length of attendance on the practice of your infirmary is required by such universities, colleges, or companies, as qualifying a student to be examined for a degree, diploma, or license to practise?

45. Have the fees for attendance on the practice of your infirmary undergone any variation, since such recognition of your infirmary, by any university, college, or company? If there has been any variation, state it.

46. What lectures are given at your infirmary?

47. What are the names of the lecturers?

48. By whom are they appointed?

49. What is the rate of fees for admission to every such course of lectures?

50. What is the time that each course lasts?

51. What is the number of pupils that attended every such course during 1831, 1832, and 1833?

52. State the emoluments that each lecturer derived from such lectures in 1833?

53. State the regulations of the hospital for admission to such lectures?

54. By what universities, colleges, or companies, empowered to grant degrees, diplomas,

or licenses to practise, are these lectures recognised as a qualification to be examined for such degree, diploma, or license?

55. When did that recognition first take place?

56. Were the fees of admission to such lectures varied in consequence of such recognition?

57. Are the medical officers of the infirmary permitted to be governors thereof? Are any of them governors?

58. What was the mortality among the in-patients of the infirmary during each of the years 1831, 1832, and 1833? State the same for the out-patients.

59. Is anatomical examination of those who die at the infirmary allowed by the governors to be made?

60. State, in detail, the income, the sources of income, and the charges upon income, the actual receipts and payments, and the balance in hand at the beginning and end of the year, for each of the years 1831, 1832, and 1833.

61. By whom and in what manner are the governors, managers, or committee of your infirmary elected? are they elected for life, or for a limited period?

62. Is there any established dietary for in-patients?

recovered. He did not suffer the least pain from the operation, but felt some uneasiness in the eye for a day or two after. He complained of pain in his head, and was ordered to be cupped on the back of his neck. A few days after he was bled in the arm, and was attacked with symptoms of erysipelas in the arm and fore-arm. Leeches were applied and the erysipelas speedily disappeared. It afterwards appeared in his leg, but there also it easily yielded to simple treatment. His health is completely re-established, but vision has not yet returned in the eye; he however can discern light from darkness much better than previous to the operation.

Stricture of the Urethra—Cauterisation.

There is a case of exceedingly obstinate stricture at present in the hospital, which has resisted all efforts at dilatation. For this case Mr. White ordered that a bougie armed with the lapis infernalis should be introduced and speedily withdrawn. Mr. White has known this plan of treatment to have been successful in very obstinate strictures.

Ulceration from Leech-bites.

Mr. White, in calling the attention of the pupils to a case of diseased knee-joint to which leeches were applied, remarked that the bites of leeches frequently, in bad constitutions, turn into formidable ulcers. He has seen a case of a gentleman who met with a severe compound fracture of the leg, to which a great number of leeches were applied. The bites of the leeches became deep ulcers, and the patient died of the excessive discharge, his medical attendants not being able to rally him sufficiently to undergo an operation.

Fracture of the Ilium.

A robust man, æt. 33, was admitted with the above injury, having fallen from a height of ten feet on the pelvis. The treatment consisted merely in keeping the patient lying in a quiet position on his back without any mechanical apparatus. In six weeks he was able to walk about the wards.

British Hospital Reports.

WESTMINSTER HOSPITAL.

Cataract—Couching.

JOHN SIMON, a young man ætat 30, of scrofulous habit, was admitted under Mr. Guthrie. About seven years ago he received a slight blow on the right eye from a soft substance, which at the time gave him no uneasiness, but was soon followed by a trifling diminution of vision. This gradually increased, and eventually he completely lost the sight of that eye. Having remained in this state many years, he at length applied at the hospital for relief. The cataract was of a whitish colour, and seemed to occupy the entire of the crystalline lens.

After due preparation Mr. Guthrie performed the operation of couching or depression. The patient being placed sitting on the ground and the operator on a chair, and having a firm hold of the patient's head, introduced the needle through the sclerotic coat, and passing it transversely towards the upper part of the lens, he broke up the opaque crystalline lens, gently disturbing it. A bandage was then bound over the eye, and the patient

LITERARY INTELLIGENCE.

PREPARING for publication, in one volume 12mo, a Dissecting Manual, containing a Description of the Bones, Muscles, Vessels, Nerves, Absorbents, and Viscera of the Body, together with their Relative Anatomy, more particularly as relates to the Arteries. By RICHARD PARTRIDGE, Esq., Junior Professor of Anatomy at King's College, London.

BOOKS.

LECTURES on the Morbid Anatomy, Nature, and Treatment of Acute and Chronic Diseases, delivered in the Theatre of Anatomy, Webb-street, by the late JOHN ARMSTRONG, M.D., &c., &c.; edited by JOSEPH RIX, M.R.C.S., London. 8vo. pp. 851. Lond. 1834. Baldwin and Cradock.

This is an admirable summary of the principles and practice of medicine, and very

far superior to most of the rival works on the subject. The excellence of the work and its cheapness will command a large circulation, which it eminently deserves.

A Series of Anatomical Plates, in Lithography, with References and Physiological Comments, illustrating the Structure of the different parts of the Human Body. Edited by JONES QUAIN, M.D., Professor of Anatomy and Physiology in the University of London, Fasciculus X. Folio. John Taylor.

The Animal Kingdom, arranged according to its Organisation, &c. By BARON CUVIER. No. 16. March. Henderson.

A Letter addressed to Henry Warburton, Esq., M.P., &c. &c., on the Grievances affecting the Medical Profession. By a JUNIOR PRACTITIONER. March. John Churchill.

CORRESPONDENTS.

Chirurgus—The list would not make a moderate 8vo.

Medicus—We do not know when the prizes proposed by the Medical Reform Association will be awarded. Our correspondent should apply to Dr. Epps, 89, Great Russell-street, Bloomsbury-square.

Juvenis—We shall attend to it.

A Dublin Reformer—An effectual reform will be made in all the medical incorporations of the United Kingdom.

M. N. B.—We are aware of the intended changes of the medical education for the degree in Cambridge, but they have not been as yet published by the University.

An Inquirer—It would be a breach of privilege to publish any of the proceedings before the Committee of the House of Commons.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXXII., DELIVERED APRIL 4, 1833.

GENTLEMEN,—I believe there is great practical utility in dividing *concussion of the brain* into the three stages, which I described in my last lecture, because the treatment should be regulated accordingly. In the *first stage*, the taking away of blood must be improper and dangerous, the powers of life being already reduced to the lowest ebb; and, consequently, an attempt to reduce them further would be contrary to the dictates both of reason and experience. The patient, in fact, is already in danger of dying, without any reaction taking place in the system; and nothing would be more likely than bleeding to render the risk of this termination still greater. On the contrary, the indication is to endeavour to rally the depressed powers of the system, for which purpose warmth should be applied to the surface of the body, and especially to the epigastrium and extremities, and stimulants to the nostrils. These I consider safer means than the internal administration of cordials and spirituous medicines, which, after the revival of the patient, always begin to have the most pernicious effects. However, some practitioners venture to give ammonia or ardent spirits by the mouth, or even to throw up turpentine clysters. From these plans I should always abstain myself, and be content with external stimulants, which can be discontinued directly they are no longer needed, without any hurtful prolongation of their action.

In the *second stage*, in which the freedom of the circulation has been restored, and a disposition to inflammation of the brain commences, all sources of excitement should be removed. The patient should be kept per-

fectly quiet in a darkish room, the head should be shaved and covered with cold applications, blood be taken away, the bowels should be freely opened with calomel and antimonial powder, and the functions of the bowels and skin promoted with saline aperient draughts. When the circulation rises a little more, the pulse quickens, and the fever and cerebral excitement have taken place, the lancet, assisted with leeches, small repeated doses of tartarised antimony, and cold washes to the head, may be said to be the sheet anchor.

Gentlemen, here you should bleed fearlessly, as often as the pulse rises above a certain point; for if you do not check the disturbance of the circulation, the inflammation in the head will certainly increase, and the patient die. It is in cases of this description that arteriotomy is sometimes proper.

The *third stage* is that of complete phrenitis, requiring quietude, bleeding, purgatives, calomel, tartarised antimony, and blisters on the scalp, or the application of the antimonial ointment to it. Afterwards, when bleeding can no longer be continued, and there is risk of effusion upon the brain, you may give calomel freely, or employ mercurial frictions with advantage.

When all risk of arterial excitement is over, and certain imperfections and infirmities of the intellectual and muscular systems remain, seemingly as consequences of effusion, or some other permanent changes in the brain, you may rub the scalp with iodine ointment.

Gentlemen, as a subject intimately connected with the consideration of injuries of the skull, I will now make a few observations on *hernia cerebri*, or *encephalocele*, as it is sometimes called, which signifies a gradual protrusion of a portion of the brain through a preternatural opening formed in the skull, either by the trephine, or by the exfoliation of a portion of bone in the state of necrosis. In children, indeed, the protrusion has been known to happen through an opening in the skull, left by its incomplete ossification. When *hernia cerebri* follows the application of the trephine, or the loss or removal of bone from other causes, some days generally elapse before the brain begins to protrude through the aperture;

and this occurrence is preceded by ulceration, or sloughing, of the dura mater, without which circumstance probably there would be no protrusion at all in ordinary cases; I mean such as follow the removal of bone by the trephine. The tumour soon attains the size of a pigeon's egg, and its circumference is pressed upon by the edges of the opening. There is great tendency to hæmorrhage from the surface of the protruded mass, and consequently the tumour is usually covered with layers of coagulated blood. In some few cases, it is curious to remark that the patient does not lose his senses; though in by far the greater number of examples, he lies in a comatose state; and if coma does not exhibit itself at first, it always comes on in the advanced stage of the disease. The immediate cause of hernia cerebri is obscure and unsettled, no completely satisfactory explanation of it having yet been given by any pathologist. It is said to arise in consequence of the removal of bone; but this is not the only cause, for if it were so, the protrusion would always follow the loss of bone, which is contradicted by experience. The ulceration of the dura mater, and other changes, appear to be concerned. The cortical and medullary portions are often distinctly visible in the protruded mass, and the pia mater is seen dipping down into the sulci, and enveloping the convolutions. Occasionally the tumour ceases to enlarge, acquires a brownish colour, pours out a foetid matter, and breaks into several pieces, which afterwards separate, and are thrown off; then granulations will sometimes arise, and the patient recover. This favourable termination, however, is rare; and I have seen so few patients get well, who had hernia cerebri, that the prognosis seems to me very unfavourable, more especially when our ignorance of its proximate cause is taken into the account. In France, it used to be the practice to dress the swelling with a pledget dipped in wine. Such an application, one would suppose, could not promise to be very serviceable; yet Larrey and others prefer it. In this country, pressure in moderation has sometimes been tried, and even the bolder method of slicing off the protruded part of the cerebral mass. As a linen compress cannot be so exactly applied as a plate of metal, I should conceive that when the surgeon means to resist the return of the protrusion, the latter should be preferred. In removing a hernia cerebri with the knife, you will frequently have profuse hæmorrhage; but though copious at first, certain cases on record show, that it stops after a short time, and is not itself productive of danger. The liberties taken with the protruded portion of brain, without any apparent ill consequences, are truly surprising: the facts show, at all events, that the superficial parts of the hemispheres will bear a great deal of injury and mutilation, without life being destroyed or recovery prevented. You will not wonder that this disease should be so often fatal, when I

tell you, that in most cases it is complicated with extensive and deep-seated injury of the brain. Dissection shows, that there is generally blackness and sloughing of the dura mater for some extent around the tumour; and that in many cases the substance of the brain has a softened and broken down appearance. A foetid dark coloured fluid is also found between the dura mater and arachnoid membrane, which latter part is often thickened and opaque.

Gentlemen, my next duty is to explain to you the *Principal Diseases of the Eye and its Appendages*, a part of surgery which is now cultivated with the most minute care, and which no surgeon who values his own reputation will neglect the study of. Were it not a subject disfigured by too many harsh and barbarous terms, I should say that it is one of the prettiest departments of surgical pathology and practice—one in which you may often actually see the changes of disease exactly as they occur, and estimate their nature and character with wonderful precision.

For the sake of method I will divide it into three parts, the first comprising *diseases of the lachrymal organs*, the second *those of the eyelids*, and the third *the diseases of the eye itself*.

With respect to *diseases of the lachrymal organs*, I may at once inform you that the lachrymal gland itself is not very liable to disease. In scrofulous children it is alleged to be occasionally the seat of inflammation and suppuration. At all events, such cases are remarkably uncommon; and many of the most experienced practitioners in this branch of surgery have never met with an instance. The inflammation of the gland, if met with, would require leeches, purgative medicines, a cold evaporating lotion, and other antiphlogistic remedies. If suppuration could not be prevented, the cold lotion should be exchanged for poultices and fomentations; and, as soon as matter is formed, a puncture ought to be made, if possible, through the conjunctiva under the outer portion of the upper eyelid; or, if this were impracticable, a puncture should be made through the skin.

Another rare disease is an *indolent scrofulous enlargement of the lachrymal gland*. When, gentlemen, I speak of any disease of the lachrymal gland, the case, whatever it may be, must be an uncommon one; and this you will be convinced of when I tell you, that at the London Eye Infirmary the reports for twelve successive years contain no example of any disease of the lachrymal gland. If you were to meet with an indolent enlargement of this organ, you would treat it with the general remedies which I have recommended for other scrofulous diseases, especially the repeated use of leeches, the compound calomel pill at night, and aperient medicine in the morning; or, what might be still more advisable, you would have recourse to friction with iodine ointment, prepared according to Lugol's formula, the

patient taking at the same time the iodine solution, made according to the directions which I specified in a former lecture. If iodine disagreed, when thus administered, which is not often the case, you might prescribe small doses of rhubarb and subcarbonate of soda, with or without the hydr. c. cretâ; or the infusion of calumba with the tartrate of iron, as alterative and tonic medicines.

Scirrhus of the lachrymal gland is mentioned by most surgical writers; but doubts are sometimes entertained, whether a certain chronic induration of the lachrymal gland, generally described as scirrhus, be truly of this nature; for the disease is remarked not to affect the lymphatic system; never to undergo malignant or cancerous ulceration, independently of that of the eyelids or conjunctiva; not to be followed by relapse after extirpation; and that the lachrymal gland is not very prone to assume any malignant change, may be inferred from the fact, that when the globe of the eye and the other contents of the orbit are extensively diseased, the lachrymal gland usually remains unaffected. The same fact is commonly noticed in cases of medullary sarcoma of the retina, even when it is advanced to that degree which makes the removal of the eye necessary. The gland may be rendered as large as, or even larger than a walnut; but when removed, its texture, though hardened, is sometimes alleged not to exhibit the peculiarities of the scirrhus structure. However, the best authorities differ on this subject; for some of them contend that the lachrymal gland, conjunctiva, and eyelids, are the parts about the eye peculiarly liable to cancer; and there is no doubt that the lachrymal gland is sometimes involved when these other parts are attacked. A truly scirrhus affection of the lachrymal gland alone is undoubtedly a very rare disease. In the examples recorded by Mr. Todd and Dr. O'Beirne, the structure of the diseased gland seems to have corresponded to that ordinarily described as characteristic of scirrhus.

What is reputed to be *scirrhus* of the lachrymal gland, is not attended with that preternatural dryness of the eye, which has frequently been supposed to be an unavoidable consequence of such a disease; for in the cases of it, recorded by Mr. Todd and Dr. O'Beirne, in the 3rd vol. of the Dublin Hospital Reports, there was actually an increased secretion of tears; an *epiphora*, as it is technically called. The symptoms characterising it, are lancinating pain in the external and upper part of the orbit, enlargement of the gland, till it forms a prominent, hard, lobulated, tumour, quite perceptible under the tense skin of the upper eyelid, and displacing the eye-ball in a greater or less degree, downwards, inwards, and forwards; dulness of the cornea, dimness of sight, double vision, dilatation of pupil, and at length complete blindness. In the worst stages, the temporal side of the orbit is dilated, or the eye so pressed

upon, as to be destroyed by ulceration and the evacuation of its humours.

As for the treatment, with the view of reducing and dispersing what is termed the scirrhus of the lachrymal gland, the means proposed are leeches, followed by a succession of blisters, alternately to the neighbouring part of the forehead and temple, or friction with Lugol's iodine ointment, assisted by the internal exhibition of the iodine solution.

Were these plans to prove ineffectual, and the tumour to become a source of considerable annoyance to the patient, or of mischief to the eye, it would be necessary to remove the diseased gland. The operation cannot be easily done from beneath the upper eyelid, as is sometimes recommended, unless an incision be made through the outer commissure, so as to let that eyelid be turned completely up, and the conjunctiva be sufficiently exposed. Hence surgeons, who have occasion to remove the lachrymal gland, have generally preferred cutting directly down to the tumour, making a crucial incision over it, raising the angles of the wound, and then taking hold of it with a tenaculum, and dissecting it out. You may conclude, gentlemen, that when the swelling is above a certain size, a crucial division of the integuments will be necessary, because a single incision would not answer the purpose of giving convenient room for its dissection and extraction.

The return of vision, and of the eye into its place again, does not always take place immediately; and the sight may, indeed, never be recovered. In one case, reported by Dr. O'Beirne, the eye resumed its proper position, and vision was restored. In another instance, the particulars of which are given by Mr. Todd, though the protrusion of the eye was gradually rectified after the operation, the blindness continued. In one or two examples, which were under Mr. Lawrence, the operation was followed by very considerable improvement of the sight.

Diseases of the Caruncula Lachrymalis.—The *caruncula lachrymalis* and semilunar fold of the conjunctiva are liable to inflammation; and sometimes matter forms in the substance of the former part. The treatment consists in the removal of the cause, which may be the pressure and irritation of the eyelashes, or the presence of some other extraneous substance; but, the most common cause is exposure to cold. The caruncula is to be frequently bathed with tepid water, and opening medicines administered. In the early stage of a severe case, a leech might be put on the caruncula; and, in the event of suppuration, a bread and water poultice, included in a little muslin bag. The abscess should be opened early, and, if fungous granulations arise, they are to be repressed with the nitrate of silver.

Gentlemen, I request your attention in the next place, to what is termed *Encanthis*, which signifies a chronic enlargement of the

caruncula lachrymalis. Two forms of it are usually described; one, a *simple* indolent swelling of the part, the other, a *scirrhus* affection of it, disposed to degenerate into cancerous ulceration, but, fortunately, so rare, that some surgeons who have had the greatest opportunities of seeing this department of surgery, have not met with a single example of it. The inconveniences, necessarily resulting from an encanthis, are considerable, as chronic ophthalmia, an impediment to the complete closure of the eye, and an interruption of the passage of the tears into the nose, by the compression and displacement of the puncta lachrymalia. Hence the tears are continually dropping over the cheek, so as to produce the complaint technically named *stillicidium lachrymarum*, which is not to be confounded with *epiphora*; for while this last consists in so profuse a secretion from the lachrymal gland, that the tears cannot wholly pass down into the nose, the *stillicidium* is a dropping of the tears over the cheek, in consequence of an impediment to their passage from the eye into the lachrymal sac. From the various causes which I have explained as accompanying encanthis, the eyesight itself must be considerably weakened and disturbed.

When an encanthis cannot be reduced by applying to it the vinous tincture of opium, or a solution of the nitrate of silver, and, especially when, from its great pain and disposition to bleed, it evinces a cancerous tendency, or, at all events, a propensity to become a malignant disease, it should be removed without further delay. Some operators pass a ligature through it, by means of which they draw it out, while they perform the requisite incisions with a small scalpel; but taking hold of it with a tenaculum will be quite sufficient to enable you to cut it away.

In the encanthis of the large inveterate kind, you may notice an elongation of it upon the inside of each eyelid, requiring to be separated with the knife in the commencement of the operation, before the main part of the tumour is separated. The surgeon should be careful not to encroach upon the conjunctiva, and, if possible, he should save a small portion of the caruncula, sufficient to prevent a perpetual dribbling of the tears over the cheek, after the cure of the disease. The eye is to be bathed with tepid anodyne decoctions, and then mild ointments, and astringent collyria, &c., are to be employed. If the granulations rise too much, apply the nitrate of silver. Although encanthis is a rare disease, its occasional formation is attested by so many good authorities, that, as far as I can judge, it deserves notice in the class of diseases we are now considering.

Of various Diseases of the Lachrymal Organs, formerly confounded together under the name of Fistula Lachrymalis.—It is only within the last few years, that any discrimination has been introduced into the

views taken by surgeons of the diseases of the lachrymal organs. Nearly all these complaints were supposed to be essentially connected with obstruction of the nasal duct; and hence its removal was generally the principal thing contemplated in the treatment. It was too much looked upon as a cause, and not as an accidental accompaniment or consequence of certain affections of the lachrymal parts of the eye. The truth is, obstruction of the nasal duct is sometimes merely the temporary effect of inflammation; and, I might say, that in the greater number of diseases affecting these parts, such obstruction either does not really exist, or, at all events, has no share in the original production of the inconveniences which the patient is experiencing.

Were you always to act in this part of surgery on the principle that an obstruction of the nasal duct is the great cause of inconvenience, you would not be showing much more judgment, than if you were to treat all the affections of the bladder and urethra by dilating the latter canal. In short, nothing can be more incorrect than the supposition, that every disorder of the organs, serving for the conveyance of the tears from the eye into the nose, must depend upon obstruction of the nasal duct, and must require modes of treatment founded upon this assumed principle.

Thus, if the disease be simply a morbid change in the secretion of the mucous lining of the lachrymal sac, the *blennorrhœa sacculi lachrymalis*, as it is termed,—or if the case be merely an extreme relaxation of the part, the *hernia* of it, as it is sometimes called, the absurdity of opening the sac with a knife, and thrusting a probe, bougie, or style down into the nose, must be too obvious to need any further comment. Good representations of the appearances of both these forms of disease are given in the plates which I now pass round for your examination.

Gentlemen, you will sometimes meet with cases of *inflammation of the lachrymal sac*, an affection which may extend, more or less, down into the nasal duct. The affection may be *acute* or *chronic*. I believe that chronic cases are far more common than acute ones. In the latter, a swelling, shaped like a horse-bean, very painful when touched, and attended with a degree of redness, presents itself just below the tendon of the orbicularis palpebrarum muscle. The swelling of the skin is at first confined to the part over the lachrymal sac, but afterwards spreads to the eyelids, which present an œdematous appearance. Now, in consequence of the lining of the sac and nasal duct becoming thickened, the passage for the tears into the nose is obstructed; so that, partly from this cause, and partly from the shrunk contracted state of the puncta lachrymalia, usually noticed at the same time, the tears do not descend into the nose, but fall over the cheek; consequently, there exists what is termed a *stillicidium lachrymarum*. However inflamed the skin may be, you can

always distinctly feel the swelling of the lachrymal sac beneath it. In healthy individuals, this kind of inflammation of the lachrymal sac rarely leads to the permanent obliteration of the nasal duct by the effusion of lymph, though, in scrofulous subjects, such a result is possible.

The pain, attending acute inflammation of the lachrymal sac and lining of the nasal duct, is exceedingly severe, indeed more violent than might be expected from the small extent of the part affected. The headach is excruciating and the fever considerable. Frequently the case advances to suppuration. The sac and the parts by which it is covered, being incapable of any further distention, sometimes slough; but, more commonly, in the middle of the swelling a yellowish soft point is observed, which soon gives way. Excellent representations of these states are contained in the plates which I now show you. Then, the collection of pus and mucus within the sac makes its way through the orbicularis palpebrarum and the integuments; but, by this opening, merely the thinner parts of the matter are discharged, and the tumour is for some time but inconsiderably lessened. Soon afterwards you will observe, that when you press upon the superior part of the sac, that not only pus and mucus are discharged from the opening, but occasionally a quantity of pure tears; a proof that the conveyance of the tears into the sac is re-established; in other words, that the action of the lachrymal puncta and canals has again commenced. This is always a favourable circumstance, as it denotes that now the only question relates to the state of the nasal duct. For some time after the discontinuance of suppuration, a morbid secretion, somewhat like pus, is kept up from the mucous membrane of the sac; but this also ceases in its turn, and healthy mucus is again formed in the natural quantity. Sometimes the opening in the sac now heals up either spontaneously or by the aid of common surgical treatment. Most frequently it contracts at first to a very minute size, through which, if the nasal duct should not have become duly pervious again, the tears and mucus will occasionally be discharged. Should this minute opening close, and the nasal duct still remain impervious, the patient is obliged several times in the day to press upon the sac, in order that the mucus and tears collected in it may be discharged through the lachrymal puncta and canals. In other instances, the swelling of the lining of the sac and duct lessens with the inflammation; the passage for the tears is restored, and a complete cure is the result.

Gentlemen, from what has been stated you will readily comprehend, that it is not every inflammation of the lachrymal sac that terminates in the production of an external opening indisposed to heal, or a *fistula lachrymalis*, as it is termed. Whether such an opening forms or not, and whether, when formed, it will

become fistulous or not, will depend very materially upon the mode of treatment adopted.

If, when the lachrymal sac is violently inflamed, the case be neglected or wrongly managed, a complete or partial closure of the nasal duct by the adhesive inflammation is very likely to be the consequence. And the same effect may be produced in the lachrymal canals, in which event, the absorption of the tears, and their conveyance from the eye into the sac, may be for ever impeded, and the patient remain during the rest of his life afflicted with a *stillicidium lachrymarum*.

Gentlemen, I will next speak of the *treatment*.

In the *first stage*, the manifest indication is to endeavour to subdue the inflammation; and it is by combating this affection, and not by attacking one, or even several of the symptoms, that you will have the greatest success in curing the complaints now engaging our attention. For instance, what would here be more absurd, than the scheme of dilatation, by the introduction of probes through the lachrymal canals into the sac, or even through the nasal duct into the nose? This would only be subjecting the inflamed parts to a new cause of irritation, and increasing the risk of greater mischief than is actually impending. Hence, instead of trying to insinuate instruments from one of the puncta lachrymalia down into the nasal duct,—a method, as I think, never advisable as a common practice, on account of its injurious effect upon the delicate organisation of the lachrymal puncta and canals,—you should have immediate recourse to antiphlogistic treatment; applying leeches freely and repeatedly to the inflamed part and its vicinity, covering it either with a cold evaporating lotion, or applying poultices and fomentations, and prescribing saline aperient medicines, followed up by calomel and antimonial powder. A very low diet will always be requisite; and, when the pain is severe, venesection should not be omitted.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XIV.

Diagnosis of Jaundice from Biliary Calculi—Proof of the Passage of the Calculus—Indications of Treatment—Rupture of Gall Bladder after the use of Emetics—Spasmodic Jaundice—Discharges of Fatty Matter—Researches of Drs. Bright and Elliotson—Connexion with Malignant Disease examined—Source of the Fatty Matter.

GENTLEMEN,—We were occupied at our last meeting, in considering the symptoms of that disease in which there is a formation of what

are termed biliary calculi; the passage of these into the common biliary duct; the possible strangulation of the duct for some time, and the consequent production of jaundice. I described the symptoms of this disease as consisting in a sudden and violent attack of pain in the region of the gall-bladder, succeeded sooner or later by the phenomena of jaundice, and in the generality of cases *occurring without fever*. Between these violent attacks the patient sometimes has intervals of complete ease; at other times a gnawing sensation continues in the original situation of the pain. It is remarkable, however, that a patient may have an interval of perfect ease between the fits, somewhat similar to the calm which occurs during the pains of labour. The occurrence of this cessation of intense suffering has been attributed to the passing of the stone into the duodenum; this, however, is by no means certain. The idea generally entertained upon this matter is that each attack of pain corresponds with the passage of a stone. How far this notion may be true I cannot decide; but this I shall impress upon your attention, that the mere subsidence of pain is no proof of the removal of the disease, *unless bile is discharged by stool or by vomiting*; but when such a discharge coincides with the cessation of pain, you may be sure that the obstruction has been overcome for the time. I need not remark to you that the smaller the calculus is, the greater the facility with which it will be discharged. You will find in some cases, that the efforts which nature makes to remove one of these concretions are quite unavailing; it lies in the gall-bladder or duct, and there remains impacted. Here its presence sometimes excites inflammation, lymph is thrown out, and the duct becomes permanently closed; in other cases it has been found to make its way into the duodenum by ulcerative absorption, and is thus discharged.

The size of biliary calculi is various. Generally speaking, their dimensions are similar to those which you see before you; but there are many cases on record of very large ones having been discharged. In the 12th number of the Medico-Chirurgical Transactions, Dr. Brayne gives an instance of one passed, which was three inches long and three and a quarter in circumference. I may, however, mention, that there is a source of doubt connected with this case. It is possible that the calculus in this instance was nothing more than one of those fatty covered concretions which are found in the intestinal tube, and which have nothing to do with the gall-bladder or its ducts. As it is my intention to return to this subject, I shall here only observe, that fatty matter has been frequently discharged in hard as well as soft masses, that it sometimes cuts like a biliary calculus, and that it may be difficult for a mere physiologist to distinguish concrete masses of this kind from gall-stones.

The passage of a biliary calculus does not

of itself necessarily imply the occurrence of jaundice: if it passes without difficulty there is none; if it happens to become impacted, then jaundice is sure to follow. It is a curious fact, that of this form of jaundice cases have occurred in which the flow of bile into the digestive tube has been obstructed for more than a year, and yet a recovery took place.

Permit me now to rehearse the diagnosis of jaundice from biliary calculi. Sudden and violent pain in the region of the gall ducts, increased by pressure, but generally unaccompanied by acceleration of pulse or fever, coming on in a person not subject to spasmodic attacks and speedily followed by jaundice. This is the diagnosis. In most of the cases described in books, and, I believe, in the majority of instances, you will find the disease to exist without febrile symptoms; but it is also true that it may be complicated with febrile disturbance, and under such circumstances you should be apprehensive of inflammation in the biliary ducts or duodenum. The importance of this will appear when you come to consider the treatment.

Now, suppose you are called to attend a case of this kind. A person of sedentary habit, who indulges in highly seasoned food and takes no exercise, gets a sudden attack; he lies, perhaps on the floor, writhing with agony; he is beginning to exhibit the yellow tinge of jaundice; he refers his pain to the region of the gall-bladder; his pulse, however, is quiet, and he has no evident symptoms of fever. Here the nature of the disease is manifest, and the first thing you have to consider is what are the indications of treatment. These are obviously threefold. The first is to guard against inflammation; for you are aware that inflammation may take place, and besides, the higher the irritation and (if I may so term it) the spasm of the gall ducts are, the greater will be the difficulty in passing the stone. The next thing is to allay spasmodic pain. We know that this pain is principally spasmodic, or nervous, because it is always more sudden and violent than that which attends common inflammatory action, and, moreover, it is commonly uncomplicated with symptoms of inflammation. The third indication is to adopt measures to favour the passage of the stone. Now these three indications, but more particularly the second and third, are, as you may perceive, reducible to one form of treatment. Whatever will relieve pain and spasm will assist in favouring the passage of the stone. If then, you happen to meet with a case of this affection in a strong robust constitution, where the pain is violent and is aggravated by pressure, and particularly where there is any sign of febrile disturbance in the system, I would advise you to bleed such a person immediately. Not that you have to combat actual inflammation, but because you have to prevent the liability to it, and because in using the lancet, you are employing a most powerful antispasmodic. The

next thing of importance, in severe cases, is the application of leeches over the region of the gall-bladder, and the same remarks apply to leeching as to venesection. You are not to suppose that the application of leeches will cure the disease; but you may be sure that it will assist materially in allaying spasm, and favouring the passage of the calculus. The bowels should be freely acted on by purgatives and enemata; you may give a brisk purgative by the mouth, and at the same time a purgative enema. After the bowels have been opened, the only thing which you can rely upon for giving relief is opium, and that in full doses. I have seen several patients labouring under this disease who appeared to me to be maltreated. The different measures for procuring relief were certainly put into practice, but not in a regular or proper manner. They first got a dose of opium, then a purgative, and lastly were bled. If you have a case of this kind to treat, bleed first, then leech, next employ purgatives, and when you have emptied the bowels, have recourse to opium. I have never employed the anodyne injection in this disease, but reasoning from analogy, I am inclined to think that it would prove serviceable, and I am aware that it has been employed with effect in that form of jaundice which depends upon hysteria. The tobacco injection also seems to have strong claims to our notice, and in this disease must prove extremely useful, from its powerful effect in reducing spasm.

There is a difference of opinion with respect to the employment of emetics. The object of their exhibition is to force the calculus through the ducts, by the shock given by the sudden and violent contraction of the abdominal muscles, and also to relieve spasm, by their subsequent relaxing effect. Some practitioners of high authority, however, state that this practice is not unattended with danger, and give cases of rupture of the gall-bladder after the exhibition of an emetic. Such an accident as this would be very likely to injure for ever the character of a professional man. I am sure the practice in some cases at least is dangerous. A distinguished medical friend of mine has related to me the particulars of a case of this kind in which the exhibition of an emetic was followed by rupture of the gall-bladder and fatal peritonitis. In this instance the case was not so deplorable, so far as the patient was concerned; he was labouring under extensive disease of the liver, and only exchanged a lingering for a sudden death; but this furnishes no excuse for a medical practitioner. If I were to hazard a conjecture, I would say that emetics can be employed with safety only in the early stage of the disease, when there is no obstruction from organic disease; for the longer the jaundice has lasted, the greater is the chance of obstruction from organic disease. Again, you should never use them where there is evidence of a distended gall-bladder. If you can feel the

tumour formed by the distended gall-bladder in the right hypochondrium, you may be sure something has been going on for a long time, and you should be cautious in giving an emetic. Never use it then where you can feel a tumour in the region of the gall-bladder. If you give it at all, give it in the early stage, and after premising venesection, leeching, and the use of the tobacco injection. I had almost forgot to mention that very signal advantages accrue from the use of the warm hip bath in this disease. I have seen cases in which the most extraordinary relief was obtained by applying twelve leeches over the region of the gall-bladder, and then placing the patient in a hip bath.

Sometimes it happens that the symptoms return again and again. Here you cannot repeat the venesection; you must employ leeches, the hip bath, warm fomentations, opium, and everything calculated to relieve pain and spasm. Watch your patient carefully, guard against inflammation, and if any inflammatory symptoms of the duodenum arise (but this is rare) take proper measures to obviate them.

A few words now with respect to what has been termed spasmodic jaundice. This form of the disease occurs independent of inflammation of the stomach or duodenum, and independent of disease of the ileum, brain, or liver. It appears to be an essentially spasmodic disease, but the situation of the spasm has not as yet been accurately determined. It is supposed to exist either in the gall-bladder, or in the biliary ducts, or in the duodenum. If the biliary ducts and gall-bladder do not possess muscular fibres, we must place it in the duodenum; but whatever may be its seat, it presents the characters of a spasmodic disease. It seems to be excited by the same cause, and yields to the same treatment as other spasmodic affections. It generally occurs in hysterical females, and in hypochondriac and nervous persons, and disappears under treatment calculated to allay nervous excitement. Its exciting causes seem to be chiefly sudden and violent mental emotions, or the taking of a quantity of indigestible food; and it frequently terminates by the discharge of flatus upwards and downwards. It resembles in a certain extent the last-mentioned form of jaundice, but differs in two particulars; first, the pain is relieved by pressure, which generally increases it in the former species. Dr. Pemberton, in his Treatise on the Diseases of the Abdominal Viscera, dwells strongly on this point. The second peculiarity is, that in this disease the attack is more sudden. In the case of jaundice from gall-stones, the patient has some degree of pain and uneasiness before the violent symptoms appear; but in this form they exhibit themselves in a sudden and unexpected manner. The disease too is accompanied with hysterical or convulsive symptoms, and there is sometimes a copious flow of limpid urine. All these circum-

stances are important in forming a correct diagnosis.

The best treatment for this spasmodic jaundice is, after acting on the bowels by warm purgatives, to use fetid enemata, and prescribe a mixture composed of ether, castor, and ammoniated tincture of valerian and opium, which are of the greatest use when the bowels have been opened. In this form, as well as that which we have been lately considering, the fact is, that if you expect any good from opium, you must not give it until the bowels have been opened. Opium and antispasmodics have, I am convinced, often lost their character for utility, from being given at a time when the exciting causes of disease are still present in full energy; and the failure of these powerful auxiliaries is to be attributed to the neglect of proper measures for reducing intense irritation. In the spasmodic jaundice, tobacco injections would be likely to produce beneficial effects. Generally speaking, however, you will not find it necessary to have recourse to such a vigorous remedy, as the disease is most commonly observed in delicate females, and yields readily to milder treatment. Indeed, it will often disappear spontaneously, and without any apparent cause.

The last form of this disease which we have to consider, is jaundice connected with an affection of the brain; and this is a very interesting and curious subject. I shall not, however, enter upon it at present, as I intend to reserve my observations on this point until we come to treat of diseases of the nervous system. I have alluded to this variety on a former occasion, and referred you to Dr. Marsh's paper on jaundice in the Dublin Hospital Reports, in which you will find several cases of it which came on as the result of disease in the head. Broussais admits that it is dependent on, and secondary to cerebral disease; but he thinks there is another link in the chain of connexion, and that this is duodenitis. He believes that we have irritation, first in the brain, next in the duodenum, and then jaundice. Several practitioners of great authority, on the other hand, assert that the cerebral affection produces jaundice at once, without the intervention of duodenal inflammation. In the present state of medical science we cannot determine this point.

A few observations now with respect to the discharge of fatty matter from the bowels. The reason why I introduce the subject here is, because it has been frequently observed in connexion with jaundice and disease of the upper portion of the digestive tube. In the last number of the *Medico-Chirurgical Transactions*, a great mass of interesting matter has been published on this subject by Dr. Bright, Dr. Elliotson, and Mr. Lloyd. I shall give you a short analysis of these papers; and I wish to impress this upon your recollection, that when you go into practice, the study of this affection would form a subject worthy of your investigations; and that any attempts on

your part to clear up the difficulties which complicate this singular form of disease will be advantageous to the cause of science.

Dr. Bright gives three interesting cases of this disease. In these the discharge was in the form of oil or semi-concrete matter,—it floated on the top of the feces, and had a fetid odour. There was also in these three cases a remarkable similarity in the pathological phenomena. The first case exhibited symptoms of jaundice, diabetes, enlarged liver, and discharge of fatty matter: on dissection the liver, pancreas, and duodenum were found diseased. The second presented symptoms of jaundice and disease of the liver, in addition to the fatty discharge: on dissection the liver was found healthy, but there was a similarly diseased condition of the duodenum and pancreas; there was malignant disease in both. Nearly the same symptoms were observed in the third case, and after death disease was found in the pancreas, small intestine, and the pylorus was in a state of extensive ulceration. In all there was chronic disease of the pancreas and duodenum terminating in jaundice, from obstruction of the gall duct, and accompanied by discharges of fatty matter from the bowels. Here are three cases, in which there is an extraordinary similarity in the symptoms and pathological appearances. Dr. Bright is inclined to think that these discharges may be connected with disease of the pylorus and duodenum, but particularly with malignant affections of the pancreas, and gives the particulars of some cases in which disease of the pancreas was suspected, and in which, from the absence of this symptom, he was induced to give a contrary opinion, which, on dissection, turned out to be correct.

Mr. Lloyd's case resembles those detailed by Dr. Bright, inasmuch as it presented the phenomena of jaundice with obstruction of the gall ducts, disease of the head of the pancreas, and contraction of the duodenum. So that you see we have here four cases in which there was disease of the duodenum and disease of the pancreas, together with the occurrence of jaundice. I may, however, mention one fact, which you should be acquainted with; in Mr. Lloyd's case the pancreatic duct was found to be obstructed by calculi.

Dr. Elliotson commences his paper by alluding to that peculiar substance called ambergris, which is frequently washed ashore by the tide in several countries, and which is supposed to be a morbid production from the intestinal canal of the *Physeter Macrocephalus*, or spermaceti whale. The quantity found in the intestinal canal of this animal is said to be enormous, and instances are mentioned, in which this substance was found to amount to 182 lbs., in the body of one of these animals. Dr. Elliotson proceeds to give cases from the records of medicine and from his own experience, in which a fatty discharge took place in the human subject. Of this he quotes cases from Mollen-

brochus and Macbini in the *Ephemerides*, but one in particular from the works of Fabricius Hildanus, which I shall briefly recount. "A pious matron of Hilden had been for a long time subject to severe pain in the stomach, which became at length much worse, when one day the pain extended all over the abdomen, and after very severe pain and suffering, she discharged about three pounds of fat, which was of a pure quality, had no smell, and was preserved by her for many years." This woman recovered perfectly. Dr. Scott, of Howick, mentions the case of a servant girl, who had been treated with purgatives and injections, under the supposition that her disease was colic, and who, after two or three days' suffering, discharged a quantity of fatty substances, about the size of nuts, beans, and peas, which burned like fat when thrown into the fire; this patient also recovered. Dr. Babington gives another case, which had been mentioned to him by Sir E. Home, in which we find that a lady, who had been suffering, as it was supposed, from gall stones, happening to take castor-oil draughts to open her bowels, passed a quantity of fatty matter. Another case is detailed by Mr. Howship, where a lady who had been attacked with pain, jaundice, and fever, passed a quantity of this substance with the subsidence of those symptoms. The fatty matter in this case was discharged after the lady had taken a pint of olive oil upon the recommendation of Dr. Simpson, of New Malton. Dr. Turner, of St. Thomas's Hospital, mentions the case of a female who laboured under an hysterical distention of the belly, and who passed quantities of this substance, specimens of which are preserved in the Hunterian Museum.

Sometimes these fatty discharges are found in the concrete, sometimes in the semi-fluid form. Dr. Elliotson mentions the case of a patient who had phthisis, diabetes, and discharge of fatty matter; thus he was at the same time passing fatty substance, large quantities of saccharine urine, and spitting up pus and softened tubercular matter. Between all these and the agonising pain which he suffered, he became in a short time completely exhausted and sank rapidly. The fatty matter discharged in this case was shown to Dr. Prout and Mr. Faraday, and Dr. Prout stated he could not distinguish it from human fat when heated. Tulpius is quoted by Dr. Elliotson as relating a case where *fat was discharged from the bowels and bladder*. Here is the quotation:—"But what do we say of Margaret Appelmania, an innkeeper, who, in her 70th year, passed precisely the same fat, both from the intestines and the bladder, and likewise without fever, emaciation, or colliquative excretion. Towards the close of the disease, however, she did become feverish, and in consequence, so emaciated, that death found her little else than a juiceless dried up corpse." A case similar to this was communicated by Mr. Pearson to Dr. Elliotson. The symptoms were

suppression of the biliary secretion and a copious discharge of *oil from the bowels and bladder*, which, it is stated, formed good soap when mixed with alkali. Dr. Prout has observed fatty matter passed with the urine, and considers this symptom as an indication of the probable supervention of malignant disease of the kidneys and bladder. The last case is from the *Annali Universali*, which is quoted by Dr. Johnson in the *Medico-Chirurgical Review* for July. In this case the patient, after fasting for a considerable time, took a quantity of indigestible food. On the evening of the same day he had an attack of vomiting: at first blood was thrown up, and then he ejected this fatty substance to the enormous amount of thirty pounds. There was, in this instance, a sudden and extraordinary emaciation, the patient was so reduced in the space of a few hours, that the skin hung in loose folds about him. He recovered in twenty days, but with great loss of bulk.

Let us inquire now what is the nature of this symptom. Is this fatty matter a morbid secretion from the liver, from the pancreas, from the mucous membrane of the stomach; or from the intestines? There are facts to show, that in certain cases this disease cannot be explained by a reference to any of these circumstances. It seems plain, too, that Dr. Bright's suggestion of referring it to malignant disease of the duodenum and pancreas, and the diagnosis which he would seem to found upon it, cannot stand here; for the symptom upon which he attempts to establish a diagnosis—a discharge of fatty matter—occurs in persons who have recovered from the disease. We cannot suppose that they have been labouring under malignant disease of the duodenum and pancreas when they have recovered; and that a recovery may take place is proved by Dr. Elliotson's cases. It is quite probable, however, that if the irritation, or whatever it be that produces this discharge, should continue, it may bring on fungoid and malignant disease; but that the discharge of fatty matter is significant of the actual existence of such a condition is not borne out by these facts. Well, are we to look upon this discharge as a secretion from the liver? I think we cannot, because we have seen that in Dr. Bright's three cases the biliary duct was obstructed by disease of the duodenum and pancreas. I may mention, too, that in some cases, where a dissection was made, the liver was found perfectly healthy, and the gall-bladder in its normal condition, full of pure bile. Taking this and the foregoing fact into consideration, we have proofs that this fatty substance, in some cases at least, cannot come from the liver. Does it proceed from the pancreas? It would more naturally come from the liver than the pancreas, for the liver does actually secrete a certain quantity of fatty matter; but there is no substance of this kind found in the secretion of the pancreas, which is considered to bear a strong analogy to that

of the salivary glands. Besides, in the case mentioned by Mr. Lloyd, where the duct of the pancreas was obstructed by calculous secretions, this fatty matter has been discharged; and hence we cannot, I think, refer it to the pancreas. Whence, then, does it come? Is it a secretion from the surface of the intestines? This is a question which it is hard to determine. We do not yet know, nor have we ever met with, that state in which lesion of structure in the mucous membrane of the intestinal canal has been followed by a discharge of fatty matter. We have discharges of serum, lymph, blood, and pus, from the surface of the intestines, according to the nature of the disease; but we know of no pathological condition as the result of which fatty matter may be produced. Again; cases of every known form of disease in the liver, pancreas, and intestinal canals, occur without this discharge at all. In the present state of medicine, the probability is that this discharge is the result of a sort of metastasis of the secretion of fat from the other parts of the body, in which it is usually deposited, to the surface of the digestive tube, where it is poured out somewhat in the same way as in cholera; the fluids of the body are rapidly absorbed and eliminated by the intestinal canal. This supposition, without attempting to bring it forward as the true solution, furnishes us with the best explanation of the case. In the case of the patient who discharged this substance by stool and with the urine, the emaciation came on rapidly, as if all the fat of the body had been absorbed and carried out of the system; here, too, the fat was discharged from another mucous surface. In the other remarkable case, where a vast quantity of this substance was thrown up by vomiting, the emaciation was so great, that the patient's skin hung in loose folds about him. When we reflect, too, that there is no recognised disease of the intestines, liver, or pancreas, to which this discharge can be referred, we cannot help believing that it is the result of a metastasis in the secretion of fat.

The next point in this matter which we have to consider is, what is the best mode of treatment. This question, I believe, cannot be answered at present; nor can our practice be anything but empirical until we have more light thrown upon the subject. With a view to increasing our knowledge, I beg of you to make this disease the subject of your practical investigations, and to have a look out for this discharge, because I believe it often occurs unnoticed, from our neglecting to inspect the evacuations.

CLINICAL LECTURES

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, &c. &c.

At the Westminster Hospital.

LECTURE XII.

Diseases of the Bladder and Urethra.

GENTLEMEN,—The first case of leucorrhage from the urethra occurred in a gentleman living in Cockspur-street, who had had a catheter passed by a surgeon of great reputation and ability in the morning, without either pain or inconvenience. On his return home he found there was a considerable oozing of blood, which continued during the day, and induced him to send in the evening for his surgeon, who was unluckily out of town; the bleeding increased in the night, and in the morning early I saw him. There were several tubs of ice and water in the room, all apparently containing a considerable quantity of blood; his face was deadly pale, the pulse scarcely perceptible; and he said he had bled a pailful, which was of course an exaggeration. The bleeding was arrested in a few minutes by pressure applied in the proper place, (on the perineum,) and did not return.

The second occurred in the case of a tradesman, who had passed a common soft bougie for himself, the point of which had caught on some small opening, and, it is presumed, penetrated into it; he bled for two days and two nights, when I was desired to see him in Paddington-street. I found him kneeling in bed, and straining violently to pass his water and the blood which came with it, but which came with great difficulty, as the bladder contained a good deal of coagulated blood, which had passed backwards into it. He was as white as a sheet, and fell back in his bed, nearly insensible, almost as soon as I entered the room, having, as he said afterwards, passed several quarts of what, as it all coagulated, he considered to be pure blood. As urine and blood coagulated together when out of the body in equal proportions, it is probable that only half of it was blood. This bleeding was also arrested in a few minutes by pressure, and did not return.

For the purpose of knowing where to make the pressure, any light, flat, and narrow, but firm, substance should be prepared, such as a piece of cork, which can always be procured. The patient should then force all the coagulated blood out of the urethra; and, as the bleeding usually takes place in these cases from that part which is anterior to the triangular ligament, pressure can readily be made upon it externally; but as it may be made a little before or behind the exact spot, in either of which cases it would be useless, the selection of that spot

must be well made. This is done by beginning as far back as possible, and gradually bringing forward the finger by which the pressure is made. At a certain point the flow or dripping of blood will be arrested, and the precise spot from which it comes will be in all probability a little behind where the finger rests, a fact which can also be easily ascertained, by carrying the finger a little backwards, when the blood will again flow. The bit of cork or pad can now be duly placed, and the patient should be desired to make pressure on it himself, and which he can often more readily do than an assistant.

When the hæmorrhage comes from the prostatic part of the urethra, cold water, rest, and an opiate will suffice to stop it, provided it has been caused by some accidental circumstance, and does not arise from disease of a fungous or malignant nature, in which cases nothing can prevent its return, or even its continuance.

A gentleman sent for me, having passed a bougie for himself, which he was sensible was not only a little larger than his usual size, but that it had also caught on some fold at the entrance of the bladder, and had passed it with a jerk; a continued bleeding was the consequence, accompanied by an urgent desire to make water, but which appeared to be blood, or nearly so. The desire soon became more urgent, and the difficulty of passing any thing greater, until at last complete retention ensued. There appeared to me to be two evils;—one, retention of urine from having passed too large a bougie; the other, hæmorrhage and irritation of the neck of the bladder from having abraded a spot on its surface, and which was augmented by the sympathy which always exists between it and any very irritable part of the urethra. In order to relieve the retention, I passed a small gum elastic catheter, which drew off a quantity of bloody urine, and relieved the irritation and desire existing at the neck of the bladder, and which soon afterwards subsided. I then directed an opiate to be given, and that he should go to bed, which he did; and although some blood oozed from the urethra, and he passed dark coloured bloody urine for twenty-four hours afterwards, indicating that some blood had found its way into the bladder, the bleeding did not return, and I attribute the subsidence of it very much to the quietude of the bladder after the distress had been removed by the passing of the catheter, and the obstruction to the passage of the blood and urine through the urethra had been removed. It is not long since you had in the hospital a case showing the nature of a hæmorrhage of this kind into the bladder, from an injury to the urethra, and filling it up so as to create great distress. The proper practice to be pursued in such cases is to inject the bladder with warm water through a catheter with a single large eye on the side and a hole at the end, or by a double catheter,

by the motions of which, in the first instance, the large coagulum may be in some degree broken up, when it is more readily dissolved by the water, which it ultimately is, so as to leave the urine quite clear in a few days, provided no more blood is poured into it.

When the hæmorrhage does not come on from any distinct accidental cause, it may be somewhat difficult to ascertain from whence it comes. An old medical friend of mine passes occasionally dark bloody coloured urine, which gave him much alarm, and on account of which he has also consulted some gentlemen, eminent from their knowledge of these diseases. The blood was supposed to come from the kidney, and that it was really blood was readily shown by coagulating a small quantity in the urine by the application of heat, and he took many different kinds of medicines in consequence without effect. As some little difficulty seemed to exist on the first attempt to evacuate the bladder, and as the bleeding might arise from the irritation caused by a small stone, it became necessary to examine the urethra and bladder. Nothing could be made out, save a slight difficulty on entering the neck of the bladder with the sound No. 12, and which part offered a positive obstruction to No. 14, surmountable only by a little management of the point of the instrument. He has, in fact, the bar, or dam, I have pointed out as occasionally forming at this part, independently of any disease of the prostate; and as he now finds that his urine is clear for many days together, and that he can always cause it to be a little bloody, either by passing a large bougie or by a little more than his ordinary exercise, he has acceded to my original opinion, that the blood comes from some enlarged veins at the neck of the bladder. He can now pass No. 14 through it with ease, and is much more free from the passage of blood than formerly. He therefore uses the solid silver sound once a-week, and has abandoned that of internal medicine, satisfied of its inutility. I was led to believe that the veins of the neck of the bladder were enlarged, first, from there being obviously some derangement of structure as well as of function at the part, and from perceiving that the veins of the nose, as well as those of the glans and prepuce, were very blue and tumid, appearing as if they did not duly transmit their blood through them, and it struck me that those of the neck of the bladder might be in the same state. The sound only did good, or does good, by preventing the increase of the bar, and thereby rendering an undue action of the bladder unnecessary; the part is, in fact, at rest.

Hæmorrhage from the neck or other part of the bladder may depend upon this simple source, or on one that is malignant. In the course of the last summer I saw a gentleman, in consultation with Dr. Prout, Sir Astley Cooper, and Mr. Brodie, who continually passed great quantities of blood, partly mixed

with his urine, and partly coagulated. The clots of blood which came away were not, however, formed of pure coagulated blood, but were mixed with shreds, and apparently a medullary matter, which left little doubt of the hæmorrhage proceeding from a fungous tumour of the bladder. He died soon afterwards quite ex sanguine, having returned home despairing of relief, and an examination after death proved the correctness of our suspicions. I had at the same time in the hospital a case of apparently equal danger, but which had a happier result. I take the history of it from Mr. Foote's case book, being one of those which obtained for him my prize of five guineas for the best selection and history of surgical cases which occurred in the hospital during the last year.

John Warrener, ætat. 42, a brass-founder, was admitted into Percy Ward, under Mr. Guthrie, June 12th, 1833. Resides in Duck-yard, Duck-lane; is a man of middle size, and rather muscular; skin rather sallow; nervous temperament; has had a gonorrhœa eleven or twelve times; has served as a marine twelve years, four years in the West Indies and four and a half in the East, but was never affected with any of the diseases of the country; he has suffered from bleeding from the bladder at occasional intervals for ten years; when it first came on he had a discharge, which he concealed, and for which he was not taking any medicine; he then came, on account of the loss of blood, under the care of the medical officer of the navy at Chatham, by whom he was attended for three or four weeks, and then discharged as incurable. He was told at the time of his dismissal that he had a diseased bladder and stricture. The hæmaturia after a time left him, and he continued well for six or eight years, when a drinking bout brought it on again. He was admitted into the hospital for retention of urine, which came on also after drinking to excess, to which he is rather partial; this was relieved by passing the catheter. Is not married; has not received any injury to the spine or abdomen; does not suffer from pain in the back or above the pubes; when the bladder is so far distended as to require its evacuation, it causes so much pain that if he is asleep it wakes him; he is immediately relieved by emptying it, and he cannot retain his water long, in consequence of the pain it gives him, which is chiefly felt near the frænum preputii, the evacuation being followed by scalding. The hæmorrhage has returned only within the last few days, and he considers that he loses a pint of blood daily; the fluid, when first evacuated, is of a bright red colour, as if it were all fluid blood, but after standing awhile a separation takes place and the blood coagulates and falls to the bottom of the vessel. The stream of urine has generally been of a good size and never twisted or double. Tongue clean; bowels open; appetite good; pulse regular, but rather jerking, 86; sleep disturbed,

15th. Mr. Guthrie passed a catheter, and said that there was a slight stricture in the urethra. He inquired concerning the shape of the clots of blood, and being told that they were round, he said that the round ones came from the bladder, but that those of a vermiform shape often came from the kidneys, or rather took the form of the ureter in their descent from it. He then ordered an elastic gum catheter, with one eye, to be passed and retained in sight, care being taken that it did not exceed the commencement of the urethra more than one inch, for fear of injuring the coats of the bladder, and that it should be passed full an inch, lest the eye or hole should irritate the neck of the bladder, for which reason he said he had them made with a hole at the end only; a common bladder was to be attached to the end of it to serve as an external reservoir, into which the fluid might continually pass, and without effort, so as to prevent any accumulation and distention of the internal bladder. He was also ordered

R. Sulph. alum, gr. iijj.
Sulph. magn, ʒiij.
Acide. sulph. dil., gtt. v.
Inf. rosæ. comp. ʒiss.

Fiat. haustus ter die summand. To keep perfectly quiet.

Mr. White, who saw him afterwards, called his pulse the hæmorrhagic one.

19th. Sleeps well, being undisturbed now by the notice to empty the bladder, which he used formerly to receive. The first night after the instrument was passed he could not keep it in, in consequence of the pain it gave him, and he was rather sulky when it was replaced; he did not at first approve of the second, or adventitious bladder, which he thus carried about with him; he is, however, now tolerably reconciled to it, and is convinced that he is improving; he suffers very little pain, and only at the frænum preputii; the stream of water is becoming clearer every day; the presence of the instrument has caused a slight discharge from the urethra. Medicines to be continued.

20th. Mr. Guthrie directed the removal of the external bladder, as it had produced the effect desired; to keep the catheter in and well plugged, its contents to be drawn off every hour; a large catheter is to be passed as the urine dribbles away by the side of the one now in the urethra.

22nd. Continues improving; his water is clear, and he passes it in considerable quantity; No. 10 catheter has been passed into the urethra.

25th. Says he is getting well fast; can retain his urine three or four hours without pain; bowels kept open by medicine. The catheter does not cause any annoyance, it is not yet of the full size of the urethra, but to be gradually increased in size, so as not to induce irritation. Medicine repeated.

29th. The catheter was altogether removed

by order of Mr. Guthrie. He can now retain his water for a long time (comparatively speaking) without pain or inconvenience.

July 9th. Dismissed cured.

I believe that as much good was done, in this case, by keeping the bladder perfectly quiet, and preventing, as far as possible, any action of it, by allowing the urine to flow always through the catheter, as by the medicine. It is a mode of practice I have followed in other cases with success; and if the sulphuric acid and alumen had not proved beneficial, I should have substituted for them the powder of galls and opium, in imitation of Ruspini's styptic, which is supposed to be made of these articles, and which I have known to be advantageously used in these as well as in other internal hæmorrhages, and particularly from the kidney, and in those which occur in females.

Dissatisfied with the application of caustic to the surface of a thick and narrow stricture, I was, fifteen years ago, induced to try the effect of its application to the internal surface, by introducing it into the stricture. My attempts did not succeed in so satisfactory a manner as I could wish, the caustic rarely doing enough to be effective. The method I adopted was, to introduce a hollow silver tube into the stricture, the single eye of which was placed in a narrowed part of the instrument, half an inch from its extremity, so that the sort of bulb thus formed, on being passed through the stricture, might, by catching or drawing it back, bring the hole or slit in the narrowed part or neck of it, just opposite the internal surface of the stricture. Into the tube a platina wire, carrying at a proper distance from its extremity a piece of caustic, moulded with a hole in its centre for the wire, and duly secured, was passed, and it looked as if it would act well, but it did not do much; and as I rarely then or do now have recourse to caustic, it has been of late altogether disused. In 1825, M. Ducamp, of Paris, published a method by which the *argentum nitratum* was to be applied to the inside of a stricture also, and he was led to believe that he could accomplish this object, however small the opening was, provided it was passable. A model of the face of the stricture having been first taken, and the opening being ascertained by a portion of the modeling composition having entered into it, a hollow tube of gum elastic, graduated by inches and lines, was passed down to it, having an opening at the end, and these openings were not all made in the centre, but as far as could be imagined they corresponded with the openings which might take place in the face of a stricture, or one was made for each particular case. Through this opening a small spoon or curette was protruded by a stillet; and as it had been filled with *argentum nitratum* in powder, which was afterwards melted by the flame of a candle, he hoped it could then be safely applied to the

inside of the stricture. It was found, however, to be difficult of application, indeed it frequently could not be applied; the curette, with every care that could be given, would not enter the stricture, and the caustic was wasted on the surrounding parts.

Lallemand, in order to prevent this evil, made an alteration in the instrument, which brings it nearly to one of the ancient English ways of using the *argentum nitratum*. It is to introduce the caustic on a stillet through a tube or hollow bougie, so that when the armed stillet is duly placed in the tube it looks like a common bougie. This is to be introduced into the stricture according to a measurement previously made, when, by withdrawing the tube, the stillet being held perfectly steady, the end of it, which is defended by a small button, forming the extreme point of the bougie, remains, and the caustic, contained in a similar spoon or curette to that of Ducamp, is exposed, and ready to be turned to any part of the circle which may require its application. This mode of proceeding is much more simple and easy of execution, as well as more effective than the other. It is liable, however, to this particular objection, that it cannot be used until a bougie of the size of No. 3 or 4 can be passed through the stricture, the effecting of which constitutes the principal difficulty in the cure, whilst all the other objections against the use of caustic, except that of making a false passage, remain in full force.

Lallemand says he has applied caustic in this manner to all parts of the urethra with success, and in one case he particularly specifies as far as the neck of the bladder and the prostatic part, at a distance of nine inches and a half from the orifice of the urethra, which was, however, naturally a long one. The relation of this cure, from page 60 to 91 of his work, is very interesting, and his subsequent remarks on the use of the *argentum nitratum* in diseases of the prostatic part of the urethra are deserving of attention, although the prejudices existing against that remedy in this country will not admit of their application, which is the less to be regretted, as the object may be attained by other, and apparently milder means.

With reference to the assertion that the use of caustic is followed by a more permanent cure than when any other mode of proceeding is adopted, much reservation is necessary. When the whole of the diseased part is destroyed by it, and it was not originally of much extent, I am inclined to believe that the statement is correct, and that there is less liability for a return of the complaint, than when the cure is accomplished by mere dilatation, although this is by no means certain. When the disease has been of long standing, and of some extent, the superiority claimed for the caustic cannot be admitted. I have three gentlemen now under my care, who had the *argentum nitratum* applied, one 40, one 35,

the other 30 years ago, by Sir E. Home; and they have had it done since, yet they all have now narrow strictures at the same place where they then existed. The occasional use of the bougie after a cure by caustic, is admitted; however, to be indispensable in most cases, even by Sir Everard Home, its firmest advocate; and the observations which have since been published, and that I have had opportunities of making, confirm, rather than refute, the admission.

**ANALYTICAL TRANSLATION OF M.
ALIBERT ON THE DISEASES OF
THE SKIN.**

BY SAMUEL FLUMBE, M.R.C.S.

*Late Senior Surgeon to the Royal Infirmary
for Children, &c.*

***Pemphigus.*—SPECIES III.**

THIS disease manifests itself on one or more parts of the body, by bullæ or vesicles of different forms and dimensions, which may or may not be surrounded by a light band of inflammation. These bullæ or vesicles, which are formed by the elevation of the cuticle, are filled with a limpid, transparent fluid. In a few days they wither and shrink, or break and leave the cutis denuded; the fragments of the cuticle form on the cutis a sort of eschar, of a blue or blackish appearance. Redness, and a blistering, burning sensation, attend the disease in its progress.

The disease is acute or chronic. The acute form generally announces itself by lassitude, and a general feeling of illness, and by wandering pains in the limbs. It arises most frequently with shiverings, or an appearance of febrile excitement on the countenance. The tongue is covered with white fur, and thirst and restlessness prevail, when a tumefaction and redness of the skin of the part shows itself. The individual attacked experiences severe pains over the whole body, the heat of skin is excessive, and the symptoms, altogether, are those of violent inflammation. Almost immediately there appears on the skin, red and purple discolorations, of a round or oval form, prominent and hard, but yielding to the pressure of the finger. These are disposed in groups, or are sometimes more dispersed, and severe sensations of pricking, itching, &c., are felt in the spots affected, whether occurring on the extremities or trunk. They show themselves on the face, eyelids, cheeks, &c., and simul-

taneously or successively, the bullæ forth, and in the course of a single night may arrive at the size of a small nut or almond. The eruption is so rapid, that often in the course of a single night, the whole body may be covered. They are then perfectly transparent, and sometimes surrounded by an areola of inflammation. The fluid is viscous and albuminous, resembling the white of an egg. When the accompanying fever is adynamic the fluid is of a deep red colour, and putrescent.

On the fifth or sixth day the vesicles break spontaneously and dry up, the cuticle becoming cracked and broken, and peeling off, shows the skin of a bloody red colour; as the disease approaches its termination, the vesicles newly formed have less volume and malignity of character, and go through the same course. The eruption, however, may extend itself so much that the patients are unable to move, and spasms and tremor of the extremities attack them. To their local pains are added severe suffering in the internal organs, and prostration of strength. Nevertheless, towards the third week the eruption dries up, leaving nothing on the skin but the appearance of crusts of a brownish colour, which eventually dropping off, leave no cicatrix, or scar, though the skin continues for some time discoloured.

The active form has many varieties. We noticed a case where the patient was attacked in the night. A female suffered from painful and irregular menstruation, and was attacked with violent pains in the head and epigastric region, constriction of the throat and chest, and other hysterical symptoms. About midnight, there arose, on all parts of the body, an eruption of vesicles, without redness on their borders. Their appearance was preceded by sensations of itching and burning. The patient slept, though agitated by frightful dreams. The pulse was irregular; but what was surprising in this case, the vesicles thus suddenly formed disappeared before morning like soap bubbles!! The fluid was re-absorbed, leaving merely redness of the spots on which the vesicles were situated.

I have attentively watched the course of the chronic form in the hospital of St. Louis, where it often appears, and have seen occasion to withdraw it from its original place among the 'dartres,' to place it here. It is truly a chronic disease, for I have seen it often con-

tinuing for several years. The bullæ appear of a mild character and form, and disappear successively. Trifling attacks only of fever take place in its course, and appear to be consequent on the local irritation.

The character of the vesicles resemble those produced by boiling water; the pain attending them is great; and the patient very often breaks and rubs off the vesicles. It is sometimes, on its first appearance, confined within a limited space on the surface, but occasionally it spreads as rapidly and extensively as herpes.

In the chronic form only it is found exhibiting the character of successive eruptions, the acute appearing and passing off speedily. When the disease is chronic, and the vesicles have arrived at their full development, they break like soap bubbles, and dry up on the skin in a wrinkled form, and sometimes the fluid is re-absorbed before rupture of the vesicle takes place.

The rapidity with which the eruption increases is different in different cases: in some it closes its career very soon; in others the vesicles do not attain their full magnitude for many hours, and some remain extremely small, and retain a globular form, the larger bearing in their external figure the resemblance to the half of an almond nut or egg. In many instances the collapsed cuticle adheres to the surface of the skin. We observe that in the progress of the disease the serous fluid changes its colour, being in the early stage a light yellow, and towards the end a livid red.

Sometimes the whole surface of the body is invaded by this disease, and is threatened with complete and entire suppuration and abrasion. An ichorous humour escapes from the corners of the eyes, which is disposed to dry and form scabs in that situation, enlarging gradually, and spreading towards, and even on, the conjunctiva. The lips swell, crack, and ulcerate to the extent of absolute deformity. The lining membranes of the digestive organs partake of the inflammatory action, and catarrhal symptoms in the same way are originated. The lining membranes of the nose, mouth, throat, &c., participate; the tongue is furred; and, in short, all the mucous membranes, more or less, participate in the disease. Microscopic examinations in

two cases have led to the discovery of an analogous affection of the intestinal canal in fatal cases; and the patients had, during the latter period of existence, bloody evacuations.

M. Alibert furnishes us with the results of the post-mortem examination of a female who died of chronic pemphigus. He says the cuticle was separated from the cutis with extreme facility, and that it showed the figure of the ampullæ, blebs, or vesicles very distinctly; that the lining membrane of the mouth was covered with aphthous eruptions, all superficial, a thin blackish pellicle being spread over each speck. The face and tongue were deeply affected by it, and the latter, partially destroyed, exhibited thick scabs, from under which issued a thick and glutinous fluid. The œsophagus, in other parts healthy, presented about its cardiac termination a slight adhesion between the mucous and muscular coats, and a serous fluid was found in the adjacent intervening cellular structure. The intestinal canal had sanious ulcerations scattered over its mucous lining, and two large vesicles were found in the colon*.

The constitutional symptoms may be such as indicate determination to, or inflammatory action of, the vital organs.

[M. Alibert details here the symptoms of such consequences at large, and furnishes us with a train of consecutive symptoms, such as are certainly never seen in this country as connected with pemphigus or pompholyx. The disease, as it is seen here, has never been found in connexion with that of vital organs, although much disorder of a certain part of them may occasionally prove an adequate cause.]

The disease is, according to M. Alibert, seen in France accompanied by the low fever of absolute starvation. His description is that of a man with a feeling heart, but too long for the pages we are able to set apart for his work.

* It may, perhaps, be unnecessary to remind our readers of our particular office, as regards the work before us, i. e. that of an analytical translator. Many of them will, as we do, entertain great doubts of the possibility of the existence of a vesicle on any part of the mucous membrane of the bowels.

Etiology.

A mysterious veil appears to conceal the causes producing this disease. Persons who have had small-pox, or other cutaneous disease, or gout, or those who suffer from suppressed menstruation, that of hæmorrhoids, are the most subject to it. The ancients thought an acrid humour existing in the blood its chief cause.

We are obliged to guess at the causes of pemphigus. Different authors have put forth their theories, and many have done so without being aware that their notions have been entertained and even printed before. A German physician entertains a notion that the fluid of the vesicle is ruinous in its character, as it has appeared where his patients have suffered from retention of urine. Another thinks that changes of the atmosphere are powerful agents; he thinks that the atmospheric air becomes at intervals of a pernicious quality, and that it irritates the vessels of the surface.

Mr. Plumbe tells us that it is occasionally epidemic, and that it appeared in that character on the banks of the Thames on each side at Chelsea, in 1816, and that it extended many miles around. Climate appears to influence very materially this disease. It is more common in England and Germany than in France, Spain, or Italy; but an instance is recorded, where an individual was never free from it from the time he left his native home till he returned.

Bad living and intemperance are always ascertained to have been among the most powerful and operative causes of this disease. The influence of the seasons of the year in producing it are equally remarkable, the disease appearing in many cases on the commencement of spring, and continuing troublesome through the course of summer. In all cases the sense of burning heat precedes the appearance of the vesicle, and there are ample reasons for considering that in many cases the latter tends to avert serious constitutional disease, or inflammation of vital organs.

Persons of sedentary habits, the occupants of prisons, those who are badly fed and hardly worked, and gourmands particularly, are most frequently subject to it. Moral causes, depressing the powers of the constitution, are also frequently traceable in individual cases.

Treatment of Pemphigus.

Our knowledge is, without doubt, not extensive as to the treatment of this disease. A more intimate knowledge of the seat of the mischief, as regards the tissues in which it originates, appears necessary. In ordinary cases, where evidence of malignity does not exist in the constitutional symptoms, it runs its course safely and calls for no material interference. The ordinary drink may chiefly consist of butter-milk and other diluents. Stimulants or sordorifics are not necessary. Cream of tartar drink is useful, and if the patient cannot obtain sleep a draught of musk and camphor has been found to procure it.

But the disease is often symptomatic of other maladies. It is complicated with many such, as synchous, catarrh, and adynamic fevers. In such cases emetics of tartarised antimony and ipecacuanha ought to be employed. If there is much prostration of strength, bad breath, and if the vesicles assume a black appearance, quinine and other tonics must be employed. If the case is that of an aged person, who has not had the advantage of good nourishment, cordials are advantageous, as have been remarked by Willan and Bateman. Mr. Plumbe advises calomel in combination with purgatives, to be afterwards followed by mild tonics. The external phenomena of pemphix approach very nearly to those of the second degree of erythema. The external treatment must not be neglected; the bullæ, or ulcerations, should be dressed with mild cerate. Starch baths and emollient pediluvia are useful. The pain is relieved by the use of decoction of poppy heads, &c., and to arrest the progress of unhealthy suppuration lotions of acetate of lead are necessary, as also the solutions of the chlorurets of sodium and lime of labanaque.

M. Alibert inquires whether this disease is idiopathic, and tending to connect the condition of the blood, or connected with hysteria, amenorrhœa, stone in the kidneys or bladder, suppression of the lochia, low fever, and scurvy? He recommends his readers to consult no less than forty-one other authors, in which list the translator has the honour of finding his own name.

Foreign Medicine.

Employment of Iodine against Mercurial Salivation.

In the Hospital of la Charité at Berlin, Dr. Kluge has confirmed, by numerous experiments, the observations of Dr. Knod, as to the efficacy of iodine in mercurial salivation. He has seen, under the influence of this medicine, the tumefaction of the glands disperse, the salivation arrested, and the mercurial ulcerations cicatrise. All these effects are manifested four or five days after the administration of the iodine, in the dose of two grains a-day, gradually increased to the amount of four grains. The formula of Dr. Kluge is as follows:—

R. Iodine, very pure, gr. v.,
Rectified alcohol, ℥ij., dissolve and add
Cinnamon water, ℥vss,
Simple syrup, ℥ss.

At first the dose each day is to consist of half a drachm of this solution, then a spoonful morning and evening.—*Allgemeine Med. Zeitung.*

Treatment of Blennorrhagia.

To cure gonorrhoea quickly, whatever be the period of the disease, M. G. A. Pitschaaf prescribes turpentine administered in the following manner:—Peppermint water, four ounces, Venice turpentine, half a drachm, solution of gum arabic, sufficient to make an emulsion, to which is to be added a drachm and a half of bitter almond water, and half an ounce of orgeat; the dose is a spoonful every hour.

If the patient is of an irritable temperament, the Dr. prefers the following formula:—infusion of half a drachm of hyoscyamus in six ounces of boiling water, Venice turpentine, half a drachm, sufficient mucilage to make an emulsion, to which should be added ℥ss of syrup of orgeat; the dose the same as in the last prescription.

When the testicles are painful, or if the patient is of a scrofulous constitution, he prescribes this other form:—

A scruple of hemlock leaves infused in four ounces of boiling water, Venice turpentine, half a drachm, sufficient mucilage of gum arabic to make an emulsion, bitter almond

water, ℥j., syrup of cinnamon, ℥j.; the dose the same.

In general, whichever form is given, it suffices to use it three or four times for the cure of the gonorrhoea, save in old discharges, where a longer continuance of the remedy is required. It is necessary that the patients should abstain from stimulating and flatulent food; for ordinary drink pure water, eau de sucrée, or Selz water; he should also wear a suspensory bandage, and take some hot baths. Opium may occasionally be required to arrest the diarrhoea.—*Journal der Pracktech Heilkund. Mai.*

Microscopical Experiments on Inflammation.

From the result of the experiments of Dr. C. F. Koch and others upon the swimming-bladder in frogs, it appears, first, that on the application of any irritant, a sensible acceleration in the movement of the blood, which circulates in this membrane and at the same time in the capillaries of the part affected, is perceived. 2nd. The movement subsides more or less promptly, this subsidence being particularly apparent after the action of energetic excitants, at which time the globules of blood are nearly in contact. 3rd. This movement of the globules is uniform in all the capillaries, save in the vicinity of large arteries, where, in consequence of the pulsation, there is an oscillation observable in them. 4th. Some isolated globules at first attach themselves to the walls of the vessels and cease to move; by degrees these globules become more numerous, form an opaque brown agglomeration, in which we can no longer recognise their form; insensibly the capillary vessels dilate in proportion, and sometimes acquire even double their volume. 5th. The number of the globules become opaque, and diminish in quantity, because they are dissolved in the serum, which they render of a red and transparent colour. 6th. In the neighbourhood of these vessels in which the blood has no longer any movement, we observe the different phenomena which are noticed in the three first experiments: at first, in the parts the nearest to these vessels the phenomena seen in the third experiment are observable; then, in the most remote parts, those of the second, and afterwards those of the first, conclusion are seen. 7th. The capillaries in which

the passage of the globules is thus arrested, and in which the calibre is much dilated, return more or less quickly to their normal state. 8th. Incisions and punctures determine the stoppage and the dissolution of these globules in the serum. 9th. When the sanguineous globules are agglomerated and their motion is diminished, quick sharp movements or any other irritant, as that which alcohol, ether, or electricity can produce, applied to the thigh of an animal, will re-establish for an instant the natural motion in the progression of the globules; but if this inflammation be slight, the globules soon return to their previous state. In general, the impression of a new excitant exasperates the inflammatory reaction. 10th. The stoppage of the globules of the blood is the more prompt the more active the stimulus is. Their collection into a mass is thus in proportion to the dilatation of the capillaries. 11th. In severe and prolonged inflammatory affections the small arteries and veins are in the same condition as the capillary vessels.—MECKEL'S *Archiv. für Anatomie und Physiologie*.

Upon the property which the Flowers of the Nerium Oleander possess of attracting Insects.

BY M. BRACNOT.

The property which many plants possess of attracting flies has hitherto been explained by the contraction which results from the irritability of the organs of generation; but M. Braconnot, who has paid attention to the plants of the Oleander tribe, has remarked, that it is in the interstices which the antheræ leave between them, that the flies are suspended by a viscid humour secreted by the stigmas, and destined to agglutinate the pollen. If living flies are placed on this part of the flower they are there retained in spite of their efforts to escape.

M. Braconnot has also remarked upon these flowers, that small spiders, too powerless to make prey even of flies, seek their nourishment in the interior of the Nerium Oleander, and there form their nests, living upon any unfortunate fly which may be so luckless as to approach the flower.—*Journal de Pharmacie*.

Active Principle of Sarsaparilla.

BY M. BALKA.

According to M. Balka, the active principle of sarsaparilla is a particular acid, to which he gives the name of *parillinique acide*, and which enjoys the following properties.

In the state of an hydrate, it resembles shells of fish; when broken down, it has the appearance of resin; on fusion it takes a brown colour; if its degree of temperature be augmented it scatters a peculiar odour, pungent and very disagreeable; when burnt, it does not leave any cinders. This acid reddens turnsole paper; if it be dissolved by alcohol, and then crystallised by evaporation, it is scarcely soluble in cold water, but placed in boiling water it readily dissolves, and causes it easily to froth. Chloride of chalk, the mineral acids, and particularly the hydrochloric acid, precipitate it in white flocculi; it differs from *acide pectique*, inasmuch as it is dissolved readily in nitric acid, and may again be collected by evaporation of the acid; with alkalis it forms soluble but uncrystallizable combinations.

The mode of obtaining this acid, is to treat extract of sarsaparilla by boiling water, which dissolves the *acide parillinique*, and then to evaporate it to dryness, and to again treat the residue with hydrochloric acid; the *parillinique acide* now becomes separated in white flocculi, which should be washed and dried.

Upon the Vinegars, and the Pyrolignic Acid of Commerce.

M. Ledoyer, in a note addressed to the Society of Pharmacy, Paris, announces that having had occasion to make some experiments upon vinegars and pyrolignic acid, he has constantly encountered portions of iron in the first, and in the others sulphate of soda, of iron, and even of copper, either together in the same acid or separately.

Treatment of Hooping Cough.

M. Sandras employs with success in this distressing affection, preparations of belladonna. The formulæ which he uses are as follows:—

Powdered leaves of belladonna, gr. ii,
Mucilage, q. s., in 8 pills, one every hour.

**CASES REFERRED TO BY M. LISFRANC
IN HIS LECTURE ON ECTROPIUM
AND TRICHIASIS.**

CASE I.—P. Dantremont was admitted into the Hôpital de la Pitié, May 21st, 1828, aged twenty-three, of a lymphatic temperament, who had been afflicted many years with double ophthalmia, which had resisted nearly every species of treatment. The conjunctiva was much injected, though in a less degree than that of the palpebra. There existed a speck on the right eye, which was very opaque, and two, of the size of a pin's head, were united on the left. Strong light caused pain, and his vision was confused. The eyelashes were horizontal, and the eyelids did not present any inversion; but on desiring the patient to close his eyes, it was easily perceived that the superior palpebra descended in front of the inferior on either side, overlapping its free border on the right to the extent of a line and a half, and on the left two lines.

Treatment.—Bleeding to two pallets, emollient collyria, half beverage, fourth of diet.

The presence of an erysipelatous epidemic, which raged during some time in the hospital, induced the professor to postpone the operation, which was performed on the 6th of June, on the left eye only, after the method of M. Janson. Simple dressing, low diet.

7th. No fever; neither inflammation or tumefaction of the palpebra; slept well.

11th. The pins have lacerated the tissue; continues as yesterday.

16th. Although the cicatrisation is not yet finished, the free border of the inferior is sufficiently carried outwards to prevent this overlapping from taking place; cauterisation by the nitrate of silver.

23rd. The transverse and the longitudinal cicatrices of the wounds are complete; the disease appears to be eradicated; ophthalmia no longer exists on this side, the opacity alone remains.

11th July.—The operation has so well succeeded, that the patient expressed a desire to have a similar one on the right, which was performed in a similar way: no bad symptom supervened; the pins came away on the 17th.

18th. The parts appear to be cicatrizing.

26th. All the small wounds have com-

pletely cicatrised, the operation succeeding as well in the latter as in the former case; vision, although improved, continues impaired from the presence of the opacities; it, however, appears gradually yielding to the employment of the tincture of opium, administered according to the precepts exposed in one of the numbers of the *Gazette Médicale*, and translated in this Journal.

The patient was dismissed on the 15th of August, freed of the double trichiasis, of the rebellious ophthalmia, and of the opacities of the cornea.

CASE II.—A. Antoine, who was admitted under the care of M. Lisfranc, July 13th, 1829. He was then labouring under a complete inversion of the inferior palpebra, with trichiasis, and severe ophthalmia. The operation was readily consented to by the patient, and performed on the 26th.

The operator first having traced with ink a line on the level with the spot where the entropium seemed to stop, in order to ascertain its extent, then exercising tractions, previously pointing out to those around him its immense inversion (being inverted nearly half an inch), and its peculiar twisted form, as if folded on itself and drawn forwards. He also remarked that he thought it the severest case on record, and that it was not without hesitation, in dread of failure, that he decided on performing an operation. The method of Kohler appeared to him the best, consequently he excised the whole integuments of the palpebra. Strips of adhesive plaster were afterwards so applied as to draw the eyelids forwards, so as to favour the formation of a narrow cicatrice. No inflammatory symptoms ensued, and in proportion as the cicatrisation advanced the inversion seemed to diminish. Care was taken to repress the luxuriant granulations by the application of the nitrate of silver.

15th August. The two internal thirds of the palpebra are reduced to their normal position, although cicatrisation is not yet completed, and the ophthalmia has nearly disappeared.

21st. Cicatrisation is gradually taking place; the palpebra returned to their natural state.

25th. The cicatrisation is completed, ophthalmia no longer exists, and on the 29th the patient was discharged cured.

CASE III.—J. Dangla came into the hospital on the 26th of May. He said that his right eye had been affected for ten years with trichiasis. The disease was produced from the inversion of the two palpebra, and had caused an almost total opacity of the cornea, so that the patient was scarcely able to distinguish day from night. The mucous membrane lining the palpebra did not present either ulceration or cicatrice; the eyelids were not oedematous. A deviation of the tarsal cartilage appeared to be the exciting cause of the affection, which is less apparent in the superior than in the inferior palpebra. The patient was operated on the 1st of June. The method of Janson was employed on the superior eyelid only; the patient was bled to twelve ounces; simple dressing and low diet prescribed.

3rd. No better. The patient experiences severe pain; the eyelid presents considerable tumefaction, which has augmented the inversion to such an extent, that the superior pin was concealed between the two eyelids, and caused much irritation. The Professor now withdrew it, which operation was attended with severe pain, on account of the difficulty which the swollen parts caused to be experienced in its exposure. Thirty leeches were applied behind the mastoid processes, and the other treatment continued.

4th. The three other pins are removed, the wound yields a copious suppuration, the symptoms of less importance are moderated.

7th. The parts have returned to their natural condition, except a slight wound which exists on the anterior surface of the palpebra.

10th. The wound presents a more healthy aspect; strips of adhesive plaster are applied to approximate the edges.

11th. The action of the adhesive plaster proving inefficacious, the strips were removed, and the simple dressing repeated.

14th. Cicatrisation is rapidly taking place from the circumference to the centre.

17th. Cicatrisation still progressive, and in proportion as it advances, the inferior eyelid may be seen to elevate.

25th. Wound completely healed; the free border of the tarsus has re-assumed its normal rectitude; the eye is no longer inflamed; the lachrymation, and the pains caused by the movements of this organ, have entirely dis-

appeared. The patient wishes to be discharged.

Here M. Lisfranc remarked, that he had reproached the method of Dr. Physick and M. Boucher for only furnishing a momentous cure. The following case will prove that what has been advanced on this subject was not without foundation.

CASE IV.—P. Guillanne, aged 19, was admitted into La Pitié on the 2nd of Feb. 1832, for a wound on the inferior palpebra, which was caused by his striking himself against the bolt of a door. This contused wound, which penetrated the whole thickness, commenced at the free border of the tarsus, immediately exterior to the inferior punctum lachrymalæ. It is five or six lines in length, and follows a direction so that its external extremity is distant two lines and a half from the same free border. This wound, accompanied with tumefaction of its edges or surrounding ecchymosis, and in every other respect sufficiently clear, was reunited by the first intention in about twelve hours after its production, by means of two needles and the twisted suture.

6th. The needles were carefully withdrawn so as to leave the threads, which adhere to the skin by the desiccation of the different fluids furnished by the wound, and combined with the heat, retain in approximation the parts, and sustain the yet tender cicatrix. But a dresser had the inadvertence to cleanse the wound, which was soon re-opened by the contraction of the palpebra. Inflammation and swelling did not permit the re-approximation of its edges, or to refresh them in order to bring them in contact afterwards; so he was obliged to await the dissipation of these symptoms. Five or six days afterwards, the inflammation having completely subsided, and the parts being considerably lessened in size, M. Lisfranc again attempted the re-union, but happily its extent was greatly diminished, and limited to at most two lines. In the hope that the cicatrice would make further progress, the operation was postponed, and the operator gave it as his opinion that it would be completed; and in a short time the patient experiencing no inconvenience, and finding himself in a comparatively advantageous condition, requested his dismissal, which was granted, but not without much regret, on the 1st March.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, March 22nd, 1834.

MR. PETTIGREW in the Chair.

Gout in the Penis—Preparations of Colchicum—Sudden Death—Delirium Tremens—Habitual Stimulus.

MR. SMITH drew the attention of the Society to rather an uncommon case, which had been related to him in the morning, namely, that of gout occurring in the penis. A gentleman, who had frequently suffered from attacks of gout in the lower extremities, which had produced the usual deposits, was suddenly seized with severe pain in the penis, accompanied by swelling of that organ; no sooner had this train of symptoms appeared than the inflammation in the great toe suddenly subsided. He had had a similar metastasis of this affection about two years previous, which had yielded to the remedies usually had recourse to in this complaint. The treatment adopted in the last attack was the administration of extract acetii colchici, and the local application of lotio saturnini. He considered this species of metastasis so very rare, that he had mentioned the case principally with the view of obtaining the opinion of the members, as to the treatment to be adopted, and particularly as to the merits of the acetum colchici, in which he placed much reliance.

MR. HUNT thought that there was scarcely any disease the consideration of which admitted so much doubt as gout: respecting the different preparations of colchicum he considered that a great error was committed in making use of wine in their formation. Some years since, a chemist of great experience had informed him, that he had made experiments upon the vinous extracts, and had found them very unsatisfactory and uncertain. The amount of the dose generally given was too large; by combining small doses of the acetic extract and alkalies he had found much benefit ensue, and he thought that those persons, who attacked this medicine, referred rather to the abuse than the use of it.

MR. GRIFFITH was in the habit of giving the colchicum in much larger doses than appeared to be the practice of Mr. Hunt; and seldom

did he prescribe less than 30 minims, with a larger dose at bed time; from the sensible benefit derived from it he was induced to consider it almost as a specific.

DR. RYAN observed, that Mr. Battley had lately introduced a new preparation of the medicine under consideration, which he denominated liquor colchici. This medicine had been used with great success in St. Bartholomew's Hospital, and he, Dr. R., had tried it with very speedy relief in two cases; but, in a third, without benefit. He deemed it worthy of remark, that Mr. Battley showed him new preparations of most of the tonics, cinchona, gentian, &c., belladonna, conium, &c., which, on being mixed with water, imparted the medicinal properties as well as in decoctions or infusions. Mr. B. also observed, that most of the tinctures in the Pharmacopœia were unchemical, and that he hoped to substitute for them the new preparations, which he had already submitted to the Royal College of Physicians.

MR. HUNT warmly objected to the employment of secret remedies. It was, he thought, derogatory to a medical man to prescribe a medicine of which he did not know the composition.

DR. RYAN wished to ask Mr. Hunt if he had ever used the liquor opii sedativus, or the James's powder. For his own part, there were few more strenuously opposed to secret remedies than himself, and so far he agreed with Mr. Hunt; but the state of pharmacy in this country was so neglected by those whose duty it was to advance it, that practitioners were obliged to use many remedies not in the Pharmacopœia.

MR. HUNT had used this remedy occasionally: in cases of great importance, about which he was particularly anxious, he always resorted to medicines in which, from knowing their composition, he could place reliance. He had not made these remarks from any hostile feeling to Mr. Battley, but merely from the general principle of disliking to make use of any remedy about which secrecy was observed.

MR. SMITH asked what was the best treatment to be observed in gouty deposits, and upon which surface of the membrane such deposits generally took place.

MR. PETTIGREW thought the deposition generally occurred on the outer surface rather

than within; in the case of Lord Holland it was however on the inner surface, and on endeavouring to remove it serious symptoms came on.

Several observations on this subject having fallen from different gentlemen,

Mr. Pettigrew mentioned the case of a man, previously in the enjoyment of good health, having been found dead in his bed: an examination was made eight hours after life had become extinct, but not the slightest trace of disease, save a small spot of ossification in the semilunar valve of the aorta, was found.

Mr. Hunt wished to know if the muscular structure of the heart was perfectly healthy.

Mr. Pettigrew said it was of the usual consistence, and was quite sound.

Mr. Hunt had asked the question from a circumstance, which had occurred some years since in a case of a similar kind to the one mentioned by Mr. Pettigrew. The surgeons who had examined the body did not find any cause for death, but, on again examining the heart, (their attention being directed to it by Mr. Hunt,) they discovered that the muscular fibres, although apparently normal, were so soft that the finger could with the greatest ease be passed through its substance.

A pause having ensued,

Dr. Ryan observed, that as there was no subject now before the meeting he would relate a case of some interest, in a practical point of view. On Monday evening last he was called to a gentleman, aged 23 years, of a very full habit, and extremely intemperate. He had been seized with apoplexy on Sunday morning, for which he was vigorously and judiciously treated. He had drank a vast quantity on the two days preceding the attack. On the evening of Monday he laboured under delirium tremens, and was extremely violent. During the consultation he was seized with a fit of apoplexy, for which he was bled, his head shaved, and mustard cataplasms applied to his feet, and a full dose of calomel exhibited. On Tuesday his delirium was increased, and the two medical gentlemen, who attended with Dr. Ryan, agreed it was nervous: tongue white and tremulous; pulse very rapid, 120; cold perspiration. He was ordered 30 m. of the liq. sed.; a fuller dose was not given on account of the tendency to cerebral congestion. In the evening he was no better, and it was

agreed to give him his habitual stimulus. He took three draughts, composed of ʒiiss. of brandy each, without much benefit; and then he continued these mixed with warm water and sweetened; 30 m. of T. opii. were added to each draught. He took the first at 10 p.m. and soon after became much more tranquil; he slept about 20 minutes, and dosed until 12, when he had a second draught, half of which he swallowed; at 5 a.m. he was perfectly collected and rational: he slept from that hour until 9 a.m. without interruption, and at 11 he was quite rational, and since then he has continued well. There was some reluctance upon the part of one of the gentlemen who attended, to the administration of opium, or stimuli, on account of the repeated apoplectic attacks, and the extreme fulness of habit [of the patient. But as the delirium was much more violent after each bleeding, and as the liq. opii. had no effect, he assented to the opinion of the two other attendants. Dr. Ryan ascribed the successful issue of this case to the habitual stimulus, and not to the 45 minims of tincture of opium, as he had now seen 14 cases in which a cure was effected by the accustomed beverage of the patient. This was better in pure nervous delirium than any medicine; and in cases complicated with congestion or inflammation it should be administered after depletion. He thought that many practitioners would have been disposed to carry depletion much farther than in this case.

Mr. Chinnock considered the case related by Dr. Ryan as one of delirium tremens; he did not coincide in the view taken of this case, nor in the particular treatment adopted, thinking that if the opium had not been prescribed, the habitual stimulus would not have produced the great benefit ascribed to it.

Mr. Hunt considered the point mentioned by Dr. Ryan particularly interesting; but, although he was perfectly aware of the value of stimulants in this complaint, he did not think the particular kind of one of so much importance.

Mr. Chinnock considered the medicine of the most importance in the treatment was opium, in full doses; bleeding appeared to him injurious, and he felt surprised to hear that such practice was pursued, in the present day, by any practitioner.

Dr. Ryan replied, that the gentleman who

called him to the case, and whose name he did not mention for reasons known to every practitioner, had called a physician of considerable eminence to another case, who bled repeatedly, and the patient died. He could mention many such cases, even of recent occurrence. If Mr. Chinnock would refer to the periodicals, during the last few years, for reports of discussions on this treatment of the disorder in question, he would find many advocates for depletion. Dr. Ryan then quoted many writers on the subject, and said that most of them advised opium. For his own part he had not found it to answer; and in one case he administered equal 960 minims in 78 hours without any effect. He then exhibited the habitual stimulus, which induced sleep within an hour, and the patient was rational next day. On two subsequent attacks he used the habitual stimulus alone, without a particle of medicine, and with complete success. It was worthy of notice, that the patient was again attacked, was bled, and died in two hours afterwards.

A gentleman observed, that in some cases the practitioner should have the lancet and brandy bottle in each hand and use them successively.

Mr. Griffith moved that the discussion be resumed on Saturday next.—Adjourned.

MEDICAL SOCIETY OF LONDON.

Monday, March 24th, 1834.

W. KINGDON, Esq., President, in the Chair.

Thoracic Disease depending on Nervous Excitement.—Treatment of English Practitioners different from that of Foreigners in Chest Affections.—Sudden cessation of the use of Calomel followed by great depression.—Administration of Stimuli in such cases requisite.

Mr. KINGDON bore testimony to the great value and importance of the remarks of Dr. Uwins on affections of the nervous system in diseases, of children. It had chanced that several of the younger members of his own family had been affected with this state of thoracic disease depending upon nervous excitement, which had caused much anxiety in his mind, and had led his attention more particularly to the subject. From what he had seen in the treatment of these cases in his own house, and

from numerous others which had fallen under his observation, he was induced to think that the less done, save with the view of lessening or calming the excited state of the nervous system, the better. Sometimes, however, it became necessary to resort to bleeding, and the method which he preferred was that recommended by Dr. Waller. Although he coincided so entirely with Dr. Uwins in his views of the cause of the disease, he must confess he had felt much surprised to find him speak so lightly of the treatment of the digestive system; for he (Mr. K.) felt convinced that the more the state of the chylopoietic viscera was inquired into, of the more importance would their treatment be found.

Mr. Moore had paid much attention to the discussion, and felt some surprise to hear so great a variety of symptoms and treatment recommended by different gentlemen. A case, illustrating the intimate connexion which nervous excitement had with thoracic and other disease, had happened in his own house. One of his children, without any apparent cause, suddenly became affected with unusual gaiety; his face was flushed, his pulse and breathing accelerated, and he was seized with vomiting and nausea. Nothing, with the exception of low diet and confinement in a dark room, was done, and the next day the child was restored to health.

Dr. Negri observed, that it had struck him, as a foreigner, that the practice of this country in these affections was very different from that pursued in his own land of Italy; there the treatment adopted was much more simple, and certainly, in his opinion, much more successful. Attention to the digestive system had always appeared to him very important, and by attention to it he thought he had seen much good ensue. The administration of calomel was, however, sometimes attended with bad results, and he therefore preferred the hydrarg. c. creta, combined with jalap. There was one medicine which he had not heard recommended, but which he thought frequently did away with the necessity for bleeding, namely, tartar emetic; it produced the necessary depression without its being of so permanent a nature as that caused by bleeding.

Dr. Whiting thought that the members, in discussing the treatment of these thoracic dis-

cases, had classed them too much together. It was not because we had general plans of treatment, but because we had particular symptoms, that particular medicines were to be given; each individual case required a separate investigation, and in no two cases did precisely the same treatment answer. Tartar emetic was doubtless beneficial in many forms of affection of the chest, but in double peripneumony, the disease which had originally formed the subject of discussion, no remedy could with safety be depended on save calomel; it was principally in cases where the disease was not very severe that the bad symptoms were produced, for the medicine might be given to a great extent when the inflammation was acute, without producing the much dreaded symptoms.

Mr. Clifton considered that the cases related by Dr. Negri entirely differed from those referred to by Dr. Whiting; in the latter the only medicine in his opinion to be relied on was calomel; the sudden cessation of the excitement, which ensued upon discontinuing this remedy, was, however, one great objection to its use, and unless great attention was paid to this point, much injury might ensue.

Mr. Proctor had seen bad consequences result from the use of tartar emetic; a state of collapse had come on after vomiting, from which the patient had not recovered. The treatment mentioned by Dr. Negri and Mr. Kingdon might be found serviceable in mild forms of disease, but in severe cases other remedies were necessary. Brisk purgatives were here most essential; and he was inclined to think that this class of medicines had not been sufficiently insisted upon by the members of the Society.

Dr. Whiting perfectly agreed with Mr. Clifton upon the absolute necessity of the gradual withdrawal of the calomel; by not attending to this, symptoms resembling hydrocephalus had come on, and the patients had sunk. It was necessary, in leaving off the mercury, to give some stimulus, and there was none so likely to prove beneficial as ammonia. In giving calomel, he did not look so much to the quantity given as to the effect produced; and indeed it appeared that the medicine, instead of acting in the usual way, acted rather upon the disease under which the body at the time laboured.—Adjourned.

THE
London Medical & Surgical Journal
Saturday, March 29, 1834.

CAMBRIDGE PETITION—LORD BROUGHAM
UPON THE UNIVERSITY MEDICAL MONOPOLIES—MANIFESTO OF THE COLLEGE OF PHYSICIANS.

THE influence of the Universities of Oxford and Cambridge upon the medical profession has always appeared to us to form a most important chapter in an inquiry into Medical Reform, and we have accordingly lost no opportunity of exposing their abuses, and of noticing any tendencies we could observe towards amendment. We set a high value upon a liberal education as the basis of professional knowledge,—an education of which the fruits should be seen in something more useful than in the trick of composing an inaugural oration of Latin superlatives, with some happy specimens of which the public has been lately favoured. In proportion, then, to the importance of a knowledge of the elements of the sciences to the medical student, and in proportion to our opinion of the ability with which they are at present taught at the Universities, was our dissatisfaction at seeing a large class of students prohibited, or discouraged, from entering their walls, and no sufficient means taking for their encouragement or instruction elsewhere. The enthusiasm of competition is awake long before the love of knowledge, for its own sake, is developed.

But it was not merely from observing, if we may be allowed the quotation,—

“Wisdom at one entrance quite shut out”
from a large portion of the community, that our indignation at the University system was excited:—the direct effect of that system upon the profession of medicine was equally calculated to awake our hostility. Their antiquated privilege of

conferring medical degrees would, however, have long since become obsolete, when they had ceased, from causes beyond their control, to be efficient schools of medicine, had not the College of Physicians bolstered up the accidents of time by its iniquitous by-law, which gives a monopoly of the Fellowship to English University Doctors.

Our readers are aware, that certain members of the University of Cambridge, comprising many of the most eminent philosophers of the age, having in vain endeavoured to induce a few antiquated men, whose thoughts are half a century old, to erase from their statutes the stain of religious intolerance, imposed by the bigotry of James I., petitioned the legislature to carry the spirit of its constitutional enactments into the public seminaries of education. We are now to record the presentation of that valuable petition to the Peers by Lord Grey. The following extract from it expresses, in forcible language, the principle upon which his Lordship amplified in a long and able speech :—

“The University is a body recognised by the law of England as a lay corporation, invested with important civil privileges, and, on that account, resting on no secure foundation, which is not in harmony with the social system of the state. Your petitioners, therefore, humbly beg leave to suggest, that, as the legislative bodies of the United Kingdom have repealed the Test Act, and admitted Christians of all denominations to seats in Parliament, and to places of dignity and honour, they think it both impolitic and unjust that any religious test should be exacted in the University previously to conferring the civil privileges implied in the degrees above enumerated.”

Of course the connexion of the Universities with the medical profession occupied the most prominent place in the discussion; and we are most happy to extract into the pages of this Journal the

admirable remarks elicited from the Lord Chancellor, which comprehend the whole subject of Medical Reform. They afford a gratifying specimen of the capaciousness of his Lordship's views, and of his exquisite skill in unfolding them. His Lordship said *,

“If a man wished to follow the medical profession, being desirous to devote his faculties and time to that most useful employment, gainful to many individuals but useful beyond almost all other professions to the community at large, he might, if he belonged to the Established Church, be enabled to pursue the profession by going to the University at Oxford, or Cambridge, by residing within his own country, and by obtaining his education there; not, however, his medical education, be it observed, because, though the two Universities are the only bodies having the power of granting medical degrees; they are, also, the only bodies which at once have the monopoly of the privilege, and of the incapacity to teach. They at once claimed for themselves the exclusive power of making doctors, and, at the same time, loudly admitted, for they proclaimed their incapacity, that they could not teach medicine.—They could only make doctors, they could not qualify them.—They could make a man a Master of Arts, by teaching him mathematics and classics, but he must learn medicine elsewhere; and, after qualifying himself by a seven years' study in another part of the world, return to the bosom of his alma mater for the purpose of being created a doctor.

“But if the same individual happened to be a Dissenter, he could not go to Oxford at all. He would, to be sure, be admitted at Cambridge; but even there he would not be able to procure a mathematical or doctor's degree. For the purpose of obtaining a degree in medicine he must quit his home, his family, and friends, and go to a foreign country. He must repair to Paris, to the Dutch Universities, as formerly used to be the case, or to the Scotch Universities; for in London, it seems, a knowledge of the medical art was not to be acquired! It should be borne in mind, that the law of Scotland was very different from the law of England, and he (the Lord Chancellor) knew

* We extract from *The Times*

of many parents, who had been deterred by that very circumstance alone from sending their children to that country for the purpose of medical education. Still, however, the Dissenter had no chance; he might go abroad, and remain there for three or four years at great expense, receiving instructions in medical science, and he might return again and find himself just in the same situation, as far as concerned the means of obtaining a degree, as when he first left. Why was he subjected to this hardship? Simply because he conscientiously differed from the religious opinions of the majority of his fellow-subjects in this part of the country. That was the reason and the only reason of the grievance under which the Dissenter now laboured, and under which he justly, and in a note not one iota louder than he ought, now complained."

Since this discussion, we are given to understand by the exclusive organ of the College of Physicians, that the College, seeing war declared upon it, and its outworks carried with such resolution in the House of Lords, as to leave no chance for the citadel at Pall Mall East, has published a manifesto in the shape of a circular to their lordships, in which it calls heaven and earth to attest its public usefulness—its disinterested conduct. It grants, forsooth, its *licence* to the doctors of any University of the earth; but, having thus provided for the public safety, it thinks itself justified in reserving its fellowship and government to English University Doctors, for the encouragement of an University education. Now it is possible to understand by what illiberal course of reasoning, the Universities may be conceived by some to be part and parcel of the Church of England: but by what obliquity of intellect can it have entered into the head of the learned President, to imagine the College of Physicians part and parcel of the Church of England? May not a physician possess "*a high moral sense*" and "*a classical education*," although he can-

not subscribe to the thirty-nine articles?—And again, if an University education was, under such circumstances of exclusion on religious grounds, to have any advantage, why not confine the privilege to the possession of a degree in arts, and allow the student, who has graduated in arts, to seek his professional degree where his profession is taught, without compelling him to return to his alma mater for his doctorate, after having studied elsewhere? But are not the excuses or pretences notoriously false? It is needless to inquire into the provision the College has made for the public wants—a handful of licentiates amongst a host of general practitioners. We are not now inquiring into the competence of the respective classes for practice; all we mean to show is, that the public is not indebted for its sanctioned medical advisers to the College of Physicians. The other pretence of superior *classical* accomplishments is unjust and false; and in all that relates to medical science, it is notorious that not five of the whole body of fellows would be enumerated among the first fifty medical practitioners of eminence in the metropolis.

GLASGOW AND ST. ANDREW'S.

IN a pamphlet lately published*, which contains a useful summary of the different medical corporations in the United Kingdom, there are some excellent remarks upon the pseudo-liberality lately evinced by the above Scotch Universities. Glasgow admits the certificate of private teachers in London or Dublin, but carefully abstains from acknowledging the private teachers of Scotland,—a palpable

* A Letter addressed to Henry Warburton, Esq., M.P., by a Junior Practitioner. Churchill, 1834.

bait to English and Irish students, for the sake of the exchequer. The same pamphlet puts the late St. Andrew's affair in a very striking light. It states, that an association of private teachers in Edinburgh, a class not recognised in the University of that city, succeeded in persuading the professors of St. Andrew's to appoint five of the Edinburgh private teachers to form a board to examine candidates for the St. Andrew's degree. The whole affair emanated from the private teachers of Edinburgh and St. Andrew's,—was merely their passive instrument for the fabrication of degrees—*Hinc illæ lachrymæ Academicæ*.

MR. GREEN'S INTENDED PLAN OF REFORM.

UPON looking at the title of a pamphlet by Mr. Green, which has just appeared*, we imagined Mr. Green must have been more fortunate than us Editors, in getting an early peep at *the* intended plan of medical reform. However, we soon found the learned Professor meant only to propound a scheme of his own, which, in truth, he does in a very transcendental fashion. He commences with the definition of a liberal profession, whereof a part is "the application of science, by the actual possessors of the same, to the needs and commodities of social man:" from this definition he elaborates the due qualifications of a practitioner, to wit, 1st. "technical knowledge," 2ndly, "scientific insight," and, 3rdly, "the character of a gentleman," as pursuing a profession, in contradistinction to a trade. With the education of the practitioner, he commences almost from the cradle. Its in-

dispensable requisities are described to be—1. "The knowledge of *words*, their definite import, and right use, as grounded in grammar, and evinced by a *correct style*." 2. "The knowledge of the elements of *mathematical science*, as the discipline of the pure sense." 3. "The knowledge of *experimental science*, as affording the requisite discipline of the senses." 4. "The knowledge of *logic*, as the laws of right reasoning, the forms of all legitimate conclusion, and the criterion of truth and falsehood." 5. "The knowledges properly *medical*," and 6. "morals." After pointing out the "*ordonnance* of mind" acquired in boyhood by the education of the senses and of the memory, he supposes the *understanding* and *judgment* sufficiently ripened at sixteen for their proper "disciplinary exercise." "Now as mathematics are the universal and necessary forms of *sensuous* experience, so does logic," &c.; whereupon the learned Professor dilates upon the properties of the higher elements of education. We are next favoured by an acute deduction of the number of professions, from the natural division of "the universal needs for the well-being of social man." The learned Professor insists that nothing short of an University education can bestow a proper degree of polish upon the student; "an University being alone capable of affording systematic instruction, a discipline that is the pledge of moral conduct and gentlemanly feelings, and alone fitted to maintain the alliance of the professions, and the unity of a learned class." Here the learned Professor parts company with the lawyer and divine, and is obliged subsequently to speak of the proposed University as "*peculiarly medical*;" and then he condenses the result of a long deduction on the character of an University into a defi-

* Suggestions respecting the Intended Plan of Medical Reform, &c. By J. H. Green, F.R.S., &c., &c. Higley, 1834.

dition, and proposes the establishment of a "*Metropolitan University, under the control and regulation of the Governing Council of the medical profession (or Medical Synod), with the power of conferring degrees.*"

On the plan of education we are constrained to be very concise at present; and we shall confine ourselves to the medical department. The student is supposed to commence his studies at eighteen; and, after three years' study, he is to be examined for the degree of *Inceptor-Graduate of Physiology*, at which time he is supposed to be educated as a general practitioner; he is then to pass an examination before the governing council, who enrol him as a *Licentiate*. After a period of three years more, devoted principally to hospital attendance, he may pass a further examination, and become a *Graduate in Physiology*, whereupon he again applies for a licence to practise from the General Council, which entitles him to the rank of *Doctor in Medicine, or Master in Surgery*, there being no distinction made in obtaining either degree, except that the examination in Therapeutics should be medical or surgical, at the option of the candidate. The Graduate in Physiology may acquire the further title of *Doctor in Midwifery*, by devoting three years to its practical study. Thus the learned Professor's scheme proposes the following distinctions:—1. *Licentiates in Medicine, Surgery, and Midwifery*, or general practitioners; 2. *Doctors in Medicine*, or physicians; 3. *Masters in Surgery*; 4. *Doctors in Medicine and Midwifery*. And further, "the general practitioner should be authorised to charge for his time, care, and attendance, without being degraded, or even permitted to degrade his profession, by a tradesman's bill in detail for his particular medicines." When we have added to these details,

that the still higher honour of a *Professorship* is reserved for men who have distinguished themselves by extraordinary talents and exertions, who should be alone entitled to fill the chairs of the Metropolitan University, or to become private teachers, we have expounded the whole of the learned Professor's plan for re-organising the profession. In most of this part of the learned Professor's scheme, we give him credit for much liberality and more judgment than we can accord to other parts of his performance. Some of the proposed arrangements coincide with opinions already advanced in this Journal.

The selection of the component members of the *National Council of Medicine*, is evidently a question of much importance. The scintillations of the learned Professor on this subject are so brilliant, that they dazzle with excessive light, and we cannot see our way through his argument. However, his conclusion is, that the *governing body should select and appoint its members*. A specimen of the argument may be useful. "Appointed, therefore, by the highest authority, and exercising an influence which evermore works a *supra in inferius*, till, as the product of its own attractive and assimilative action, a correspondent ascension gradually takes place; a college thus framed, perfects itself into a circle, ever working from above, yet ever returning on itself." After this matchless illustration, we have only to add, that professors, doctors in medicine, masters in surgery, and doctors in medicine and midwifery, are, according to the scheme, alone eligible to the council.

Thus have we enabled our readers to form some conception of the learned Professor's plan of Medical Reform; but we can convey but a very inadequate idea of

the pleasure to be derived from a perusal of the pamphlet. Amidst much to provoke mirth, there will be found much matter for reflection.

PARLIAMENTARY INQUIRY.

THE investigation is going on with increased spirit—not a cranny will be left unsearched. We are not at liberty to print the particulars; but we must say, the examination which took place this week, gave infinite satisfaction to an immense number of the profession who were present. Mr. Warburton shows himself a master of his subject, and merits the full confidence of every friend of Reform.

Reviews.

A Treatise on the Composition and Medical Properties of the Mineral Waters of England, with instructive Observations on the Drinking of the Waters, and the Use of the several Baths. By SIR CHARLES SCUDAMORE, M.D., F.R.S., &c. Second Edition, 8vo. pp. 215. London: 1833. Longman and Co.

Cases Illustrating and confirming the Remedial Power of the Inhalation of Iodine and Conium in Tubercular Phthisis, and various disordered States of the Lungs and Air Passages. By SIR CHARLES SCUDAMORE, M.D., F.R.S., &c. Second Edition, 8vo. pp. 227. London: 1834. Longman and Co.

ABOUT three years ago, the first edition of this work appeared; and we animadverted on the conduct of the author in withholding from the profession his mode of employing the inhalation of iodine. Some of our contemporaries followed our example, and Sir Charles was compelled to publish his formulæ. We also proved that Dr. Murray, now Sir James Murray, physician to the Marquis of Anglesey, had anticipated, as may be seen by referring to his *Essays on Heat, Humidity, &c.*, 1829.

We are happy to state that the author has

now placed his statements fairly and fully before the profession; and expresses his firm conviction, that the inhalation of iodine is productive of results highly and permanently beneficial in consumption, but fails in some cases. The author narrates examples of cure and of death after the use of the remedy he advocates, and he avoids the empiricism of some of the profession and quacks, who can prevent and cure all cases of consumption. The formulæ used by Sir Charles is the following placed in a glass vessel:—

℞. Iodinæ, gr. v.,
Potassæ hydriodat. gr. iij.,
Aquæ distillatæ, 3v.,
Alcoholis, 3ij.,
Tinct. conii, 3vi *.

Sit mistura.

The conium is added before using the inhalation, to diminish the irritating effects of the iodine. The remedy is used twice or thrice a-day, together with ordinary medicines, and friction to the chest.

Some well-marked cases of pulmonary consumption are detailed in which a cure was effected. We have inquired of Sir James Murray how far his subsequent experience enabled him to speak in favour of the ioduretted inhalation, and his reply was, that it fell short of his expectations. M. Gannal's cases, cured by chlorine, seem also well-marked, and yet we have not found his remedy of any benefit in the third state of consumption. We used it in a case of a lady, who was afterwards seen by Dr. Davies, of Broad-street, without any effect, and also in another, with Mr. Matthews, of Hunter-street, Brunswick-square. In both cases much irritation was produced, and the inhalation was discontinued.

When we consider the pathology of tubercular consumption, the situation of tubercles, their immense number in different states of development, progress, and termination, and the number of abscesses of various sizes in the lung, we confess we entertain no hope for a patient in the second or third stage of the disease.

Were we able to discover incipient tubercles, and saturate the system with iodine, we might fairly expect great benefit, and perhaps a cure; but when a lung becomes

* A saturated tincture.

studded with tubercles and abscesses of various sizes, and there is every probability of the existence of similar disease in the other side of the chest, we may palliate but cannot cure consumption. We agree with our author, that much relief may be afforded, and life prolonged, by remedies, in cases of consumption; but we cannot believe that a cure can be established when such an important organ as a lung is totally destroyed by disease.

This second work, on the mineral waters of England, is the best extant, though silent on those of other countries. The author might have supplied the defect, as he would have enhanced the value of his treatise, and made it one of reference and authority. In a future edition, we think he ought to avail himself of this hint, and he will find the matter ready to his hand in an article on the subject published in the London Encyclopædia and Medical and Physical Journal. He would also find much matter in the new French Dictionaries of Medicine.

Annual Report of the Royal Jennerian and London Vaccine Institution. 1834.

Traité de la Vaccine et des Eruptions Variolieuses ou Varioliformes, ouvrage rédigé sur la demande du Gouvernement. Par M. J. B. Bousquet, &c., &c. 8vo. pp. 367. Paris, 1833. J. B. Balliere.

It is highly gratifying to every philanthropist to learn that the great Jennerian discovery sheds blessings on the human race in all parts of the civilised world, as appears by the lengthened correspondence from all parts of the globe, addressed to Dr. Epps, the Medical Director of the London Vaccine Institution. The profession in all countries are almost universally in favour of vaccination; but there are some few against it. Those conversant with the history of the ravages of small-pox, of the deformity produced by it, of the loss of vision, excitement of scrofulous abscesses, congestions and inflammations of the brain, lungs, &c., cannot for a moment sanction the transmission or diffusion of the cause of such evils. If medical practitioners informed those prejudiced against vaccination, of the dangers it prevents, very few could, we apprehend, be found to resist the conviction of its inestimable value. We very much regret that prejudices still exist, even in this

country, as will appear by the following extract:—

“As to the progress of vaccination in this country, your Board has still to express their regret that much prejudice against this boon still exists, and that, in distant parts of England, even *medical men* perpetuate, by all means in their power, the small-pox. And the Board think it their duty, though painful, to record the following extract from a letter received by Dr. Epps, the Director, from J. D. Hawker, Esq., Surgeon, of Stratton, Cornwall:—‘I live in a remote district, where a strong prejudice exists against the vaccine practice, and, like all prejudices, cannot be supported when the simple question is asked, ‘Why do you object to it?’ The small-pox has just broken out amongst us like a plague, and though endeavouring to promote vaccination, being a strong supporter thereof, I have been compelled to inoculate for the small-pox nearly 200 children. The prejudice against vaccination is supported very strongly by some *medical men* here. I should imagine,’ adds Mr. Hawker, ‘that this is almost the only place where vaccination has been completely shut out till I came down.’

“In regard to this gentleman, the Board have the pleasure of stating that he has delivered a lecture at the Stratton Literary Institution in behalf of vaccination, which lecture Mr. Hawker has published, and it will, no doubt, be productive of much good; and the Board, considering the exertions of this gentleman in the cause of vaccination, beg to recommend him to the Governors as worthy of being elected an Honorary Member of the Institution.”

We have only space to add, that the work of M. Bousquet is ably executed. It will be perused with advantage by every medical practitioner.

British Hospital Reports.

ST. GEORGE'S HOSPITAL.

Ulcers of the Rectum.

Clinical remarks by Mr. Brodie.—These are neither common or uncommon, and are more usually met with in private than in hospital practice. A patient will come to you, for instance, complaining of severe pain after voiding each fecal evacuation, but there will be discharge; and if you make an examination,

you will not find any swelling or abscess; but just within the back part of the gut, and opposite to the os coccygis, you will feel with the finger a rugged, rough, irregular ulcer, but very superficial and small. The patient will complain of great pain on the examination being made. If nothing is done for such an ulcer as this, you will find all the symptoms and the pain after every stool to become much aggravated; the diameter of the ulcer will become enlarged and increased, the patient's countenance will become sallow, and the powers of the constitution will suffer. Well, how is such an ulcer as this to be treated, and how is it to be healed? Local applications can hardly be made use of in such cases as these, nor am I, indeed, aware that any such are useful in these affections. You may give the Ward's paste, which acts locally; if you give it by the mouth it becomes mixed with the fæces, and is thus applied to the part. It may be mixed with soap, in the proportion of 1 to 3, and used as a suppository, a method which will sometimes be found both useful and advantageous to the patient, and under which treatment I have known some recover. It is, however, generally best to give this medicine internally, the size of a nutmeg, three times in the day, and the confectio sennæ with sulphur every night to soften the fæces, as hard ones only tend to aggravate the disease. The Ward's paste (confectio piperis nigri) only effects a cure, after being used for a long time; it acts as a stimulus to the parts affected, and alters their action, and heals them. But when you are called to a patient in whom the disease is in an advanced state, you will generally find the Ward's paste fail, and in such a case what are you to do? I will tell you:—The disease is *always situated just above the sphincter muscle, and opposite to the point where this muscle is attached to the os coccygis*. The ulcer strains and irritates it; and if you divide the sphincter ani you cure the disease. Divide the muscle, then, with a straight probe-pointed bistoury, and set the parts free, and you will find that the ulcer will speedily heal. There are some cases in which a minor operation was contrived for the cure of this affection by Mr. Copeland. He proposed to divide the mucous membrane, and some few of the muscular fibres above and below the ulcer. This was done by introducing the finger into the gut, as a director, and passing upon it a probe-pointed bistoury, with which the parts were divided. This operation answers very well in slight cases, in which, indeed, it is only to be used, and causes no inconvenience or confinement to the patient. I have known it fail, and I have known it succeed. This division of the sphincter ani muscle is not recommended in books. When I was a student, this operation was neither known or practised. M. Roux told me it was first performed by his father-in-law, M. Bourcier; I then performed it, and have continued to do so frequently ever since. I con-

sider it an operation highly important to the science of surgery, and of great advantage to patients.

Division of the Sphincter Ani.

There are many cases in which this is useful; I will mention some of these to you. In ulcers of the rectum (as above), this operation is useful. In cases of eruptions and psoriasis about the margin of the anus, you may try the use of common fuller's earth, or the unguentum zinci, or the unguentum hydrargyri nitrates to the parts; but if this is neglected, you will find fissures forming around the margin of the anus, which frequently are very troublesome, but these you may soon relieve by dividing the sphincter ani. There are cases in which the sphincter ani becomes spasmodically contracted, the patient has great pain after every large stool of hard fæcal matter, which pain frequently extends up to the loins, and will last for many hours, and render the patient's life miserable. On examining the part, you will find the sphincter muscle very much enlarged in volume, and contracting strongly on the finger. This affection is more commonly met with in women than in men. It is generally an hysterical affection of the part, which lays the foundation of the disease, which renders the part prone to spasm. In these cases the division of the sphincter ani relieves the patient completely of the disease. I have known a patient cured of this affection by these means, after it had existed for five years. Attention should, of course, be paid to the state of the bowels and the general health.

Cases sometimes occur, in which from some cause there exists an ulcerated communication between the vagina and rectum, and the fæces pass through this ulcerated opening into the vagina. Now a thing of this kind happening in a young woman makes her very miserable. Mr. Copeland had a case of this kind, in which he divided the sphincter muscle for its cure. He reasoned very properly on it; for, said he, if it cures ulcers of the rectum, why should it not also cure this. He performed it in two cases, and in each the ulcerated opening closed up. I saw a case of this kind under the care of Dr. Jewel, and here there was a thickening of the textures and the ulcerated orifice. I divided the sphincter ani in this case, and the ulcer had almost entirely healed, and I was led to believe that she was well, but I find that she passes fæces through the bladder.

There are another set of cases, in which the division of the sphincter ani is useful: I allude to cases of fistula in ano. This fistula in general runs through the substance of the sphincter muscle in its whole course. Now, why does not such a fistula heal? Because it is situated in a muscular part, and for the same reason that an abscess in the calf of the leg will not heal. The common cure of such a fistula is to divide it, and heal it to the bottom,

but the cure is frequently very tardy. I have known the disease to last after the wound has been healed. A fresh sinus will sometimes form, if it be crammed too full so as to prevent the matter from escaping. In operating on such cases, I lay the fistula open to the gut; if it be large, I divide the whole substance of the muscle; if small, I merely separate some of the fibres, so as to set the neighbouring parts at liberty. I have done this operation now for some years, and I find the occurrence of a fresh sinus to be a very rare thing. The management of such cases is indeed very easy and simple; there is seldom any particular dressing required: put a poultice on the part, and let the bowels remain costive. There is no fear of union by the first intention, as the action of the muscle keeps the divided surfaces apart. In some cases I use no dressing whatever, and merely touch the parts occasionally with the nitrate of silver. In performing this operation, you should only divide that side of the muscle in which the fistula is situated. Never divide the muscle on the side towards the vagina, for if you do the patient will for ever afterwards have incontinence of fæces. If, however, the fistula be in a female, and be situated anteriorly, you should make a double oblique incision so as to form a valve. You should have a piece of lint by you dipped in Ruspini's styptic; and should any hæmorrhage occur, keep this plug pressed against the part for the space of a quarter of an hour: the wound soon heals. I never yet met with a case in which there was incontinence of fæces.

VOL. V.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXXIII., DELIVERED APRIL 8, 1833.

GENTLEMEN, — There are two principles which I wish particularly to inculcate: 1st, that it is not every inflammation and temporary obstruction of the lachrymal sac and duct which require the introduction of instruments down the duct into the nose; 2nd, that when the obstruction is permanent, you should puncture the sac, and attack the obstruction in this manner. This is much better than any display of ingenuity by throwing lotions into the sac through the lachrymal puncta and canals. We are thus, I think, more likely permanently to destroy the right action of these delicate organs, than to remove the stoppage of the flow of the contents of the sac into the nose.

In the *second stage*, when resolution is no longer practicable, the cold lotion may be laid aside for emollient applications; and as soon as the sac is so distended with mucus and pus, that the centre of the swelling begins to soften, and a fluctuation to be perceptible, a puncture should be made large enough for the ready discharge of the contents of the sac. Having made an opening, I would avoid immediately passing a probe from the puncture down into the nose, and merely inject tepid water with a lachrymal syringe gently down the nasal duct, a plan which may be repeated every day if the fluid pass into the nose. This seems to me better practice than the premature employment of a probe. It is the method I have followed at the Bloomsbury Dispensary, and in private practice, with frequent success, and never with any harm, even though other measures may become necessary.

When, by means of antiphlogistic treatment, the inflammation of the membrane

of the sac has subsided, and by this and other measures the mucous secretion from it has been brought into a healthy state, and all the induration has disappeared, you may then think of adopting some plan for the re-establishment of the passage through the nasal duct, if it should not have already become pervious under the previous antiphlogistic treatment, as often happens when the inflammation is of a healthy kind.

What I have now said principally relates to acute inflammation of the lachrymal sac; but, gentlemen, this part is still more liable to *chronic inflammation*, the external appearance of which form of disease is well represented in this coloured engraving. Sometimes, and especially in scrofulous subjects, the lachrymal sac becomes considerably distended with mucus, without any previous active inflammation in it. The inconvenience first noticed, is a weakness of the eye, from the tears collecting at the internal canthus. Whenever the patient looks at minute objects, he finds a tear ready to drop over the cheek; and, to relieve himself from this annoyance, he is obliged to press upon the sac, so as to force its contents down into the nose. In this case, the nostril is generally remarked to be in a drier condition than it ought to be in the natural or healthy state of the lachrymal organs. Things go on in this way a considerable time, until it is at length found, that the tears cannot any longer be made to descend by pressing upon the tumour in the corner of the eye; but, instead of doing so, they regurgitate by the puncta lachrymalia, mixed with pus and mucus.

Now, gentlemen, I wish you to remember that the mucous membrane of the sac is the chief seat of this chronic inflammation. Sometimes the lachrymal canals, the sac, and the nasal duct are all affected together, and sometimes merely the lachrymal canals. After a certain period, the effects of the inflammation generally extend, more or less, to the mucous membrane of the eye-lids, and even to the eye itself.

In many individuals the complaint disappears during summer, but returns at the commencement of cold or wet weather.

In the course of this disorder, the lachrymal sac is indeed liable to occasional attacks of more active inflammation, in which the skin may become red and painful, and the nasal duct and lachrymal canals completely obstructed. Unless the inflammation be resolved, the swelling points and bursts, and the opening, if neglected, becomes a true *fistula lachrymalis*.

The case now under consideration resembles the other, arising from acute inflammation of the lachrymal passages, but modified by scrofula. Hence, it often follows the state of the constitution left after measles, small pox, and scarlet fever.

The *treatment of chronic inflammation of the lachrymal sac* consists in first endeavouring to remove the inflammation; and, if you succeed in this purpose early enough, you will prevent suppuration and ulceration of the sac, the formation of a *fistula lachrymalis*, as it is called, the nasal duct will not be permanently obstructed, and the tears and mucus will resume their proper course into the nostril.

If, after the cure of the inflammation, the passage should not be free, and the sac remain distended, you may endeavour to press the fluid with which it is filled down into the nostril, placing the finger for this purpose between the puncta and the sac, and pressing from the puncta towards the nose. This should be done occasionally, either by the surgeon or the patient himself. You may also instil into the corner of the eye a few drops of a lotion containing 2 grs. of the nitrate of silver, or from 2 to 4 grs. of the sulphate of zinc, to an ounce of distilled water; and the application may be repeated every day or every second day, according to circumstances.

I think Mr. Lawrence has given very judicious advice on this subject, especially with reference to the mischief likely to accrue from irritating the lachrymal puncta and canals with syringes. You should be content, as I have said, with merely dropping the collyrium into the inner canthus of the eye, whence it will be absorbed into the lachrymal sac and ducts, so as to operate upon the mucous membrane. When you drop any collyrium into the nasal angle of the eye, in order that such fluid may be absorbed by the lachrymal puncta, the patient should lie upon his back, and continue quietly in this position for a short time after the operation.

When the palpebral conjunctiva and Meibomian glands are affected, you may employ salves, the best of which are the ointment of the nitrate of quicksilver, in the proportion of one-third of it to two-thirds of spermaceti ointment; the red or white precipitate of mercury ointment in the proportion of one scruple of the powder to one ounce of lard; or the nitrate of silver ointment, from five to ten grains to an ounce. Undoubtedly, when suppuration cannot be prevented, emollient poultices and fomentations are advisable; and,

as soon as the abscess is distinctly formed, you make an opening in the sac by an incision or a puncture.

On examining the nasal duct, we now generally find it contracted at one or several points; and, for the removal of the obstruction, you are next to introduce a common silver probe, and then employ an instrument called a *nail-headed style*, in order to remove the disposition of the passage to close again. This instrument may be worn for an unlimited time without any material annoyance. The eye-lids being drawn outwards, so as to put the orbicularis palpebrarum on the stretch, you may make a puncture in the sac with a lancet, and a large quantity of mucus and puriform matter will be immediately discharged. A common silver probe is then to be passed into the sac, and thence down the nasal duct as far as the nostril, so as to clear away the obstruction. It should be introduced horizontally, till it touches the nasal side of the sac; it should then be raised into a vertical position, and its point directed downwards and a little backwards. If its point meet with any obstruction, you must not immediately conclude that there is an obliteration of the duct; you must press it down a little more strongly, but not with violence, turning it round between the fingers, and giving it different directions. In this way the obstacle may frequently be overcome, and the probe will suddenly descend. The probe is then to be withdrawn, and a little tepid water injected; after which, the style is to be introduced sufficiently far to bring its head in contact with the skin, or the court-plaster, which is sometimes applied when a freeish opening has been made. However, I see no utility in making a formal extensive incision: all that is required is a puncture to let out the matter, and to allow the style to be introduced; and what proves the inutility of a larger wound, is the very circumstance of its being requisite to close a part of it with court-plaster, as soon almost as made, namely,—all that portion which exceeds what is necessary for the ready passage of the style.

In a few days the wound heals up, with the exception of the opening filled by the style. The instrument is to be withdrawn two or three times a-week, and tepid water, or some slightly astringent lotion, injected through the nasal duct.

After the style has been worn a little time, the *blennorrhœa of the sac*, as it is termed, disappears almost entirely. The tears and mucus, absorbed by the lachrymal canals, would seem to be conveyed along its surface through the nasal duct, and thus the functions of the parts being restored, the inflammation and discharge quickly subside.

Sometimes, after the style has been worn one, two, or three months, it is discontinued, and the opening heals up; but a relapse takes place, and it is necessary to introduce the style again, and to continue it for some

weeks longer. What proves how little inconvenience is commonly felt from its presence is, that the patient will often express a preference to wearing it a very long time, rather than subject himself to the slightest chance of a return of the disorder.

When the head of the style is covered with black sealing wax, it causes also little or no disfigurement. The instrument must be taken out and cleaned occasionally, however long it may be worn. After the parts have become habituated to it, I find that taking it out once a-week is quite sufficient. If left in too long, it may be so corroded as to break in the part.

When the style, on being first used, creates much irritation, it is better to withdraw it, and, after clearing away all obstruction in the ductus nasalis once more with a probe, you must be content with injecting tepid water through the nasal duct by means of Anel's syringe, using at the same time leeches, emollient applications, and aperient medicines. Instead of a style, metallic tubes are employed by some practitioners; Baron Dupuytren prefers them: probably they answer as well as the style; but the latter is what I have been accustomed to. I will show you the operation on the dead subject in the course of a few days.

Gentlemen, when a probe cannot be got through the obstruction in the nasal duct at the first trial, you may leave the probe, or, what is better, a piece of catgut, or bougie, in the passage, and daily repeat the attempt to overcome the stoppage. If the obliterated state of a portion of the nasal duct still prevents success, the right practice consists in perforating it by means of a small triangular perforator. This is a much better method than drilling a hole in the os unguis, and removing any portion of this bone with forceps, or destroying it with the cautery. If the perforated part of the duct should not admit of being kept open after the style has been worn a long time, the patient must continue to wear it or a small gold tube. Caries of the os unguis, so frequent formerly, is now rarely met with, a proof that it was generally occasioned by wrong treatment.

With respect to *general treatment*. In scrofulous cases, chronic inflammation of the lining of the sac and nasal duct will sometimes not yield, unless an attempt be made to improve the state of the constitution by alteratives, tonics, and iodine medicines. You may also usefully combine with such treatment blisters behind the ears, or a seton in the nape of the neck, and iodine lotions, according to the formulae given by Dr. Lugol.

Hernia of the lachrymal sac, or the relaxation of it, left after the cure of chronic inflammation of it, is to be treated by compression, joined with the application of an astringent lotion, both to the outside of the tumour and to the internal surface of the sac. Compresses are to be wet with it, and some of it

dropped into the lacus lachrymarum, and left to be absorbed by the puncta.

Hydrops of the lachrymal sac is the swelling produced by the accumulation of mucus in it, in consequence of an obstructed state of the lachrymal canals and nasal duct. The natural secretion of mucus in the sac goes on, but as it can neither be discharged by the lachrymal canals, nor by the nasal duct, it collects, so as to form a tumour, which has been known to attain the size of a pigeon's egg. In the treatment, the sac is to be opened, its contents discharged, and injections used, for removing any thick mucus which may remain. A little lint is to be put into the sac, and next day the lachrymal canals and nasal duct are to be examined, and the causes of the accumulation having been ascertained, you are to aim at their removal.

Obstruction of the Puncta Lachrymalia and Lachrymal Canals.—Gentlemen, the puncta lachrymalia are sometimes congenitally deficient; such a case, I scarcely need tell you, is hopeless. Sometimes the puncta and canals are constricted, but pervious; and occasionally they become blocked up with calcareous matter deposited from the tears. The most frequent cause of their obstruction is a thickening of the membrane lining them, a consequence of previous inflammation.

When calcareous matter is present, it must be removed as soon as its presence has been detected by means of Anel's probe, made expressly for the purpose of examining the lachrymal puncta and ducts, and for removing any slight obstruction in them. When they are stopped up with mucus, they may, with these instruments, easily be made pervious again.

If you are examining the superior puncture and lachrymal duct, the point of the probe is first to be introduced from below upwards, till it reach the angle of the canal. It is then to be directed circularly downwards and inwards.

In examining the inferior duct, the point of the probe is first passed from above downwards, and then horizontally towards the sac.

When with these instruments you cannot decidedly make out whether there is an obstruction in the puncta or not, you may drop into the lacus lachrymarum a drop of an aqueous solution of saffron, while the patient lies upon his back. If the canals execute their office, you will see this coloured fluid disappear, without falling over the cheek.

When the puncta and canals are completely obliterated, the case is irremediable; for, were you to think of forming new puncta and ducts, you could not give them the organisation essential to make them of any use.

You will also meet with cases, in which a *stillicidium lachrymarum* arises from atony and relaxation of the lachrymal puncta and canals, in consequence of previous inflammation, or the too frequent irritation of them with probes and syringes. The puncta are seen to be widely open, and incapable of contraction.

For the cure of this form of diseases, Beer recommends an astringent collyrium, made of distilled water and a small proportion of the sulphate of iron, and camphorated spirit, or the tinct. opii. It is to be dropped out of a pen, or director, into the inner angle, frequently in the course of the day; the patient being kept for some time on his back after each application.

In old persons, this kind of stillicidium is attended with more or less separation of the lower eyelid from the eye. It may be somewhat relieved by astringent collyria; but, I believe, is rarely cured.

From what I have said, I hope you fully understand, that a stillicidium may be caused by any obstacle to the passage of the tears into the nose, as polypi or fungous tumours of the nose pressing upon the nasal duct. It has likewise been known to be produced by diseases of the antrum, exostoses, caries of the bones of the face, &c.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XV.

Acute and Chronic Hepatitis—Pathological Differences—Effect of Climate—Disease in Animals—General and Local Symptoms—Character of Fever—Pain of Shoulder—Use of Pleximeter—Complication with Jaundice—Resolution—Abscess—Various Openings of the Abscess—Cicatrisation.

GENTLEMEN,—I propose to-day to draw your attention to the subject of inflammation of the liver. This is the disease which you meet with in books under the general name of hepatitis, but it is of great importance to distinguish between acute and chronic hepatitis for this reason;—acute hepatitis implies something specific, an organic change, the nature of which is well known and accurately defined; but chronic hepatitis implies nothing of this certainty of the nature of organic change, inasmuch as there is no single one of the recognised disorganisations of the liver, which may not, and have not occurred, with chronic hepatitis as an exciting cause, or a prominent symptom. When we speak of acute hepatic inflammation, we speak of a disease, of which the structural lesions are sufficiently understood; but when we treat of chronic hepatitis, we treat of a disease in which there may be a great variety of organic changes. Chronic irritation of the liver may in one patient be followed by the development of hydatids; in another by cancer, or tubercle; in a third by hypertrophy of one or both of its elementary tissues; in a fourth by atrophy; and in a fifth by abscess; so that under the chronic form of hepatitis we may have many different lesions comprised. Under

the acute form we have only vascularity, softening, yellow degeneration, and suppuration. These, which are the ordinary results of acute hepatic inflammation, are the same as the results of active inflammation of other parenchymatous organs.

It is an interesting fact, and connected with the predisposition to acute diseases of the abdominal viscera in warm climates, that acute hepatitis is much more prevalent in those countries than it is here, and this is particularly true with respect to the East Indies. You recollect, in one of my lectures, I alluded to the greater susceptibility to disease, the extraordinary nervous excitability of the digestive mucous membrane in warm latitudes, and hence that a large proportion of the diseases of those climates was characterised by the predominance of inflammation in the stomach and intestines. The same thing occurs with respect to the organs which are connected with the digestive tube, and hence it is that diseases of the liver and spleen are so frequently met with between the tropics. A very remarkable fact, bearing on this point, has been mentioned to me by Staff-Surgeon Blest. He states that, in the East Indies, hepatic disease in animals is no unusual occurrence; that *animals brought to India from more temperate climates are peculiarly subject to it*, and that in them it is a common cause of death. He has seen many cases of hepatic abscess in dromedaries and horses under these circumstances; a fact of great interest when considered with the liability to *tubercle* in animals brought from *warm climates* to these countries. In these countries acute hepatitis in its highest degree is a rare disease; in fact so rare, that it is only in our own time that any thing like a series of cases, by which you could compare the disease in these countries with a similar affection in others, have been published. A series of cases by Louis, and another by Dr. Graves and myself, published some time since, are all that we have on the subject. It is somewhat extraordinary that a sort of epidemic tendency to acute hepatic inflammation and the formation of abscess occurred in these countries about the middle of the year 1828. Up to this period abscess of the liver was looked upon as a very rare disease in Ireland; a case of it was met with in hospital once perhaps in twelve months or two years; but at the period to which I allude, almost every great hospital in Dublin had several cases, and in the Meath alone we had a great number, out of which seven or eight proved fatal.

We have now to consider this acute inflammation of the liver:—and first, with respect to the symptoms. Were I lecturing on pathology merely, I would commence with the organic changes; but as I have chiefly kept in view, during my present course, the practice of medicine, I shall begin by detailing the symptoms. You will get a good idea of the symptoms of acute hepatic inflammation by dividing them into local and general; by doing

this you will simplify the matter and acquire accurate and defined notions of the disease. Now, the local symptoms are, pain in the region of the liver, tenderness over the affected organ, and a degree of tumefaction perceptible to the touch; pain, tenderness, swelling,—here are the local symptoms. What are the general? Inflammatory fever and lesion of the digestive function; and in addition to this, if the case be severe, you have functional derangement of the respiratory and cerebral systems. You have then, in a case of acute hepatitis, the general symptoms of inflammatory fever with lesion of the digestive function, and if the case be severe, of the respiratory and even cerebral systems, the local symptoms being pain, tenderness, and tumefaction.

Now, with respect to the character of the fever which accompanies this disease, it is in all cases nearly the same, and here we come to an interesting and curious fact. You recollect, that in speaking of gastro-enteric inflammation, I alluded to the nature of the accompanying fever, and stated that it was (commonly) of a low character, and that there were no local inflammations in which the fever was so often typhoid as in the affections of the gastro-intestinal surface. This, I believe, has been one great cause of the ignorance of medical practitioners with respect to gastric and enteric inflammations; they have been most commonly looked upon as cases of typhus and treated accordingly. In acute hepatitis, however, we do not observe this typhoid prostration. Though closely connected with the gastro-intestinal system, the liver does not in its acute inflammatory state, produce the same manifest depression of the vital powers. On the contrary, we have, in the early period of the disease in this country, high inflammatory fever, hot skin, and full bounding pulse; a state in which few would be afraid to employ the lancet with boldness. Patients labouring under acute inflammation of the liver, generally have high sympathetic fever, a full, strong, and accelerated pulse, with the local symptoms above described, and, in addition to these, we frequently observe bilious vomiting, considerable thirst, derangement of the bowels, and scanty high-coloured urine. The tumefaction is more or less evident, and when this is accompanied by severe pain, there is considerable difficulty of breathing, a circumstance which sometimes occasions this disease to be mistaken for pleurisy. There are two remarks to be made on this subject. In the first place, it sometimes happens that acute inflammation of the liver and of the lower part of the lung occur at the same time, particularly where inflammation attacks the diaphragmatic surface of the liver. Here you frequently have an extension of the inflammatory process to the corresponding surface of the pleura, or the two diseases co-exist from the first. Under such circumstances, disputes as to which organ is engaged are often unnecessary. Again, in the early period, and when

the attack is acute, the diagnosis of inflammation of the diaphragmatic surfaces of the liver or pleura is comparatively of little consequence, as both demand the use of calomel and opium, leeches and the lancet; and, in the early stages at least, both are amenable to the same treatment. But it is not so in the chronic stage of either. Here the diagnosis is of great importance; and when I come to treat of pleuritis I shall draw your attention to some researches of mine on this subject, which I hope have set this question at rest.

The pain which accompanies acute hepatitis varies much in situation. Sometimes it is felt in the shoulder, sometimes under the short ribs, sometimes in the loins, and frequently in the epigastrium. You have all heard of pain at the top of the shoulder as a common symptom of liver disease, in fact, so common as to be looked upon by some as a pathognomonic symptom. I believe that a great deal too much stress has been laid on this circumstance. It is now discovered, that so far from being a constant, or even a common, symptom, it is one which is of exceedingly rare occurrence. I have never seen a case of acute hepatitis with pain in the shoulder; I have sometimes observed it in chronic, but never, to my recollection, in acute cases. Andral states, that it is very seldom met with; Dr. Mackintosh says the same, and, if I recollect aright, looks upon it as a symptom not worth inquiring about. Now, I have seen some medical men who considered this pain in the shoulder as a diagnostic of such value, that if it happened to be absent they concluded there was no hepatic disease. The fact is, that it is anything but constant. You may have it in some cases, particularly of chronic hepatitis, and not in others; besides, it frequently depends upon other causes—for instance, upon pneumonia of the top of the right lung, or it may be caused by incipient phthisis, aneurism of the arteria innominata, or right subclavian artery, and other diseases. It is of very little consequence whether it be absent or present; and the only reason why I dwell upon it is, to show you its real value as a symptom.

There is one remarkable circumstance connected with the pain of an acute hepatitis. In one case, you will find that the pain is very acute and constant, in another, that little or none is felt; and when you come to investigate the cause of this after death, it generally happens, that in cases where the pain was violent the inflammation existed on the surface of the liver, and in those where little suffering was experienced, deep in the substance of that organ. This is a curious fact; but it may be looked upon as an illustration of a general law, *that if we consider inflammatory affections of the solid viscera, we shall find that the more superficial the inflammation, the more painful it is; and, on the other hand, the more deep-seated it is, the more is it latent, so far as pain is concerned.* Thus: if you take a case of inflammation of the sub-

stance or central parts of the brain, you will find that the disease is to be recognised often not by pain, but by the lesions of the sentient and locomotive powers; whereas, in inflammations of the membranes, on the surface of the same organ, one of the most prominent symptoms is agonising headach. In the next place, go to the lung,—take a case of deep-seated pneumonia, and contrast its almost painless character with the lancinating torture of an acute pleuro-pneumony. In pneumonia the pain is dull, and scarcely complained of; but pleuritis, unaccompanied by acute suffering, is extremely rare; in fact, where you have the signs of inflammation of the parenchymatous tissue of the lung, with sharp pains in the chest, you may very safely make the diagnosis of pleuro-pneumony. The same absence of pain is by no means unusual in inflammatory affections of the mucous membrane of the intestines; but if the inflammation should chance to extend to its peritoneal investment, you will have this state rapidly exchanged for one of intense suffering. So it is with respect to the liver: disease on the surface of that organ is attended with severe pain; but enormous destruction of its deep-seated parts may take place, and your patient complain merely of a sense of uneasiness.

A late author on hepatic affections, Dr. Bell, who has written a treatise on the diseases of India, describes two forms of acute hepatic inflammation, which are different as to their seat and character. In one of these, which he terms *sero-hepatitis*, the disease is on the surface of the liver; in the other, which he terms *puro-hepatitis*, it exists in the centre. In the sero-hepatitis, he states that the patient is attacked with sudden pain in the region of the liver, and this is so severe that even the weight of the bed-clothes is insupportable; the patient cannot bear to turn or lie on his left side, from the pressure exerted in that position on the inflamed organ. But the deep-seated, or puro-hepatitis, may go on in such a latent manner that the first symptoms you have of the existence of liver disease are those which mark the occurrence of suppuration. Neither the patient nor his medical attendant will have reason to suspect inflammation of the liver, until the constitutional and local symptoms of the suppurative process direct attention to that organ. Such are the statements of Dr. Bell, which I believe to be correct, as they are supported by the concurrent testimony of many persons who have practised in India, with whom I have conversed on this subject. Mr. Annesly makes the same assertion; and such was our experience in the succession of cases of hepatic abscess which were under treatment in the Meath Hospital during the year 1828.

The next symptom which we have to consider is the tumefaction of the liver, and this, gentlemen, is one of considerable importance. In order, however, to estimate the extent of this tumefaction with any degree of accuracy,

you must take one preliminary step, and that is, to have the bowels fully evacuated. If the intestines are filled with feculent matter or gas, you cannot do this in a proper manner. A few hours before you make your examination, give the patient a full purgative draught, assisted, if necessary, by a strong purgative enema. In this way you empty the belly of collections of feculent matter and æriform fluid, and then you can with certainty and satisfaction ascertain the extent of the swelling. You will then be able (when your patient is laid in bed), perhaps, to see at once the extent of the tumefaction, particularly where the parietes are not thick or loaded with fat; at all events you will be able to feel it with your hand, and in every case you can ascertain it by mediate percussion with the pleximeter. I do not know any more important adjuvant, in making out the diagnosis of an enlarged liver, than the use of mediate percussion. For instance, suppose you have a patient labouring under acute hepatitis, and that the tenderness of the organ is so great that he cannot allow you to make the requisite degree of pressure to ascertain the extent of the swelling; take the top of your stethoscope, apply it over the region of the liver, make use of light percussion, and you will find, with the greatest accuracy, how far the tumefaction of the liver extends by the dulness of sound heard over the inflamed organ and exactly limited to it. In this way you can make a most satisfactory examination, without giving your patient any pain, and this is a matter of some importance, as you will meet with many cases in which there is exquisite tenderness, and where the patient will not bear the slightest pressure. I would advise you, therefore, to practise this mode; it gives little or no pain, it is exceedingly simple, and I have not the slightest doubt of its accuracy. Now the value of this tumefaction, as a sign of the existence of hepatic inflammation, depends very much on the recent nature of the attack. If a man who was in perfect health a few days back complains of pain in his right side, and has a tumour in that situation, it is to be presumed that this tumour does not depend upon the presence of a collection of fluid in the pleura, and consequently that the tumefaction is not produced by an empyema. Then, if in connexion with fever and pain in the right side you can ascertain the existence of a tumour in the region of the liver, and that it has occurred within a short space of time, you may be pretty sure that it is not an empyema, but an inflamed and enlarged liver.

Jaundice has also been considered as a symptom of hepatic inflammation, but it is one which is by no means constant. Again, you may have most extensive hepatitis with slight jaundice, and universal and intense jaundice with trifling or no hepatitis, and what is equally singular, you may have very little perceptible disease of the liver with scanty secretion of bile; and, on the other hand, the

liver may be burrowed with abscesses, and at the same time you find bilious stools, and after death the gall-bladder may be found filled with pure healthy bile. I thought at one time that I could explain the presence or absence of jaundice in cases of hepatitis, by supposing that where it occurred the jaundice was the result of inflammation of the gastro-duodenal mucous membrane; and to prove this, I drew up a table of cases, of which one half were complicated with jaundice and the other not. I found, however, that in a great number of cases, where the tube was free from disease, the hepatitis was complicated with jaundice; and in a similar number of cases, where the same circumstances were observed, the tube was in a state of disease. So that we may have, as you perceive, hepatitis and jaundice with and without disease of the intestinal tube; and whether we look to the cases of hepatic inflammation, unaccompanied or complicated with jaundice, the state of the gastro-intestinal mucous membrane throws as yet no light on the subject. It appears, then, that the occurrence or non-occurrence of gastro-duodenitis does not explain why it is that in one case of hepatic inflammation jaundice is a prominent symptom, and in another is completely absent.

In some cases of acute inflammation of the liver the natural secretion of that organ seems to be totally annihilated. A curious case of this kind occurred under the care of Dr. Graves, in the Meath Hospital, where the slightest trace of bile did not exist in the gall-bladder, which was filled with a transparent mucus. In some instances you will find plenty of bile discharged, in others none; in some patients the stools are observed to be clay-coloured, or very faintly tinged with bile, in others they are healthy, and natural in colour as well as consistence. From our own experience, and from studying the series of cases published by Louis, we have come to the conclusion, that neither the presence nor the absence of bile in the stools affords any positive or useful information as to the different stages of this disease, its progress or termination.

Acute hepatitis terminates in a variety of modes. It may terminate by resolution,—here the organ returns to its former healthy state without any appreciable change of structure or function; it may terminate by the formation of matter,—here we have suppuration and abscess; it may terminate in gangrene; and, lastly, it may, without the occurrence of suppuration or gangrene, pass into chronic hepatitis, of which the result may be a variety of morbid changes in the organ itself. When the patient is so fortunate as to meet with the first of these terminations, the fever, pain, and tumefaction, gradually disappear. On making an examination with the pleximeter, you will find that part of the belly which was rendered dull by the tumefied liver becomes clear on percussion; you

will find also that the dulness of the lower part of the chest on the right side is removed, the patient can breathe without any difficulty, and lies on the affected side without inconvenience. But when the disease passes into the suppurative stage, the train of phenomena exhibit a marked difference. What we generally observe under such circumstances in this country is, that there is a change in the constitutional symptoms; the fever, which has been hitherto inflammatory, now becomes hectic. The pulse continues quick, but is diminished in strength and volume; the countenance becomes pale and collapsed, the patient feels languid, restless, and disposed to sweat, and his perspiration has a sour smell. He may also have a miliary eruption, and this continues for some time, with an increase or persistence in the size of the hepatic tumour. When these symptoms appear, there is every probability that matter is forming or has been already formed. The patient then begins to complain of increased weight in the region of the liver, and in some cases the integuments over that organ are swollen and slightly discoloured. I have observed that in some instances the pain concentrated itself in one point, and in this situation it was afterwards found that abscess had formed. These are the ordinary symptoms which usher in or accompany the suppurative stage of hepatic inflammation; but there are also cases, even in this climate, where this marked change of symptoms is not seen, and where abscess forms rapidly and with symptoms which might be supposed to belong to the early period of the disease. This, however, is particularly true with respect to hepatic abscess in the East Indies.

I believe I mentioned in a former lecture a very curious fact, namely, that it has been often found impossible to salivate persons labouring under hepatic abscess, so that the presence of matter or not in the liver may be determined by the circumstance of the patient being susceptible or not of the full effect of mercury. The liver in this case seems to illustrate that pathological law which I alluded to in speaking of dysentery, that the more intense an inflammation, the greater is the difficulty of producing ptialism. My friend, staff-surgeon Marshall, and also Mr. Annesly, agree in stating, that it is exceedingly rare to find a case of hepatic abscess in which the salivary glands have been affected by mercury, and our experience of the disease in this country exactly coincides with their opinion. It has been also observed, that hepatic abscess may form in an insidious and latent manner, when it happens to be complicated with disease of other organs. This affords us an illustration of a law already laid down, that the more complicated an affection is, the more obscure is its character. Again, we may, as the result of acute hepatitis, have one or two vast cavities formed in the substance of the liver, or we may have a number of very small abscesses. I

recollect a case which occurred some time ago near this city; the patient exhibited the symptoms, and was, in fact, supposed to labour under intermittent fever. After some time death took place, and on dissection a number of small abscesses were found in the liver, of which, during life, there was no symptom, except that which I have just mentioned.

When an hepatic abscess attains a certain magnitude, it has a tendency to burst and discharge its contents. If it escapes externally, it makes its way in a great variety of directions, sometimes in the epigastric, sometimes in the hypochondriac, sometimes in the lumbar region, and there are cases on record, in which the matter has burst in the right axilla, by a sinuous passage beneath the integuments of the chest. When it bursts internally, it sometimes perforates the diaphragm, and gets into the cavity of the pleura, or what is more commonly the case, into the substance of the lung. The matter of an hepatic abscess very rarely gets into the pleural sac, and hence we very seldom have an empyema as the result of this occurrence, because the pleura being extremely liable to adhesion as a consequence of the inflammatory process, and the passage of matter being always preceded by inflammation, the opposed surfaces of the pleura become glued together by coagulable lymph, which prevents the hepatic pus from getting into the pleura, at the same time that it favours its passage into the lung. The opening into the lung is one of ordinary occurrence; many cases of it are on record, and serious as the lesion may appear, it is, perhaps, one of the best modes in which hepatic abscess may terminate by internal opening. Many persons have recovered after such a termination, and I have seen myself three cases in which it was certain, and a fourth in which it was probable, that the matter had been expectorated by the mouth, with a favourable issue. We are, then, as far as the records of medicine and our experience in the Meath Hospital go, warranted in looking on this termination as a favourable one. Hepatic abscess may also open into the pericardium, but this is very rare, there being only one case of this kind, which is given by an American author. It may open into various parts of the intestinal canal, the stomach, duodenum, and colon; it may also discharge its contents into the right kidney, into the vena cava, or into the peritoneum, and thus cause violent peritonitis and death.

The diagnosis of these different openings of an hepatic abscess is easy, and founded on the same principle, the occurrence of new and extraordinary symptoms connected with the adjacent viscera which were not before diseased,—symptoms of a sudden discharge of pus from or into these organs. Suppose you have a case of hepatic abscess, and that during the progress of the disease the patient has sudden and enormous expectoration of purulent matter, without any preceding signs of inflamma-

tion of the lung, it is probable that the abscess has opened into the lung; or suppose that during an attack of acute hepatic disease, your patient is all at once seized with nausea, and vomits a quantity of purulent matter, and immediately after this you perceive that the tumefaction of the liver subsides. Here the matter has been discharged into the stomach, in other cases you have it discharged into the duodenum or colon. Again, you may have instances where the matter gets into the peritoneum; here you may observe the occurrence of rapid peritonitis. So that in all cases of this kind, the diagnosis is founded on the same principle, *the occurrence of discharge of pus from or into organs which previously had been considered to be in a healthy state, and this coinciding with a subsidence of the original tumour.*

In persons, who under such circumstances recover, it is natural to expect that cicatrizations should exist in the liver. Louis states that he has never seen this; with respect to our cases of hepatitis, we can only say that the fatality of the disease has afforded us no opportunity of investigating this point of morbid anatomy. Mr. Annesly, however, in his work on the diseases of India, has given drawings exhibiting this appearance. I recollect one case of a man in the Meath Hospital, who had been a soldier in the East India Company's service, and had been treated for liver disease; this man died of phthisis, and on dissection the surface of the right lobe of the liver was found puckered, forming a hollow with a cartilaginous basis, strongly resembling what we might suppose to be the cicatrix of an abscess.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES
OF INFANTS AND CHILDREN,

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE XVI.

Diagnosis of Infantile Diseases.

GENTLEMEN,—There is much difficulty in distinguishing the diseases of children, for at this early age, there is no language or reason on the part of the sufferers to assist us; and at a later period, when the power of speech is developed, we can place little, if any reliance, upon the answers to our interrogatories. We are therefore obliged to employ the signs of diseases of adults—symptomatology—and to deduce our inferences from this and pathology, so as to arrive at correct conclusions.

It is highly necessary to direct your attention to the usual symptoms of disease in the different organs of the body. Some writers have said, that the state of the countenance, the degree of plumpness, or emaciation, the

state of the breathing, the deviations of the stools from the orange-yellow colour, the drawing up of the lower, and the convulsive motions of the upper limbs, are the chief indices of infantile diseases; but were we to content ourselves with this catalogue, we should take a very superficial and imperfect view of the subject, and form very wrong and dangerous conclusions. We shall therefore consider the matter somewhat more minutely.

The difficulty of arriving at a correct diagnosis in diseases of children, is one of the chief causes of the great mortality among them. Such was the opinion of Wichmann, (*Ideen Zur Diagnostick, Einleitung*). It is an ancient axiom, "a knowledge of a disease is half the cure." Baglivi has well observed, "*Antequam de remediis statuatur, primum constare oportet, qui morbus, et quæ morbi causa: alioquin inutilis opera, inutile omne consilium*,"—before we attend to remedies, it behoves us, in the first place, to determine the disease, and the cause of it, otherwise all our efforts and consultations are useless. Let us suppose a superficially informed practitioner, who confounds diseases whose symptoms are somewhat similar, but whose causes and treatment are totally different, and we can easily comprehend the dangerous and fatal consequences of such mistakes. If we contrast this dangerous empiric with a well-informed practitioner, who, at one view, discovers the nature of the disease, and employs the proper treatment, we shall observe how different are the results of the practice of these individuals; how beneficial that of the one, how destructive that of the other.

I need scarcely observe, that it requires a perfect knowledge of physiology and pathology to form a correct diagnosis of diseases, and of therapeutics to remedy them.

Physiology teaches us the natural functions of the body, circulation, respiration, digestion, innervation, &c.; pathology the disordered states of these; and therapeutics the indications and means of cure. We must, therefore, apply these sciences to the different ages, sexes, habits, temperaments, idiosyncrasies, or peculiarities of constitution.

Judicious and scientific physicians follow a regular method or order, in their examination of the symptoms of disease. They first observe the state of the countenance, tongue, pulse, digestive and respiratory systems. They successively pass in review, the functions of the body, ascertain the local symptoms in the head, chest, abdomen, and in any other part which may be affected. Patients seldom suppose that their medical attendants can, in a few minutes, comprehend the nature of their complaints; but this is easily done, in the majority of cases, by well-informed practitioners.

When we look at a patient, his countenance not only indicates the condition of his general health, but likewise of his intellectual faculties and muscular power; the state of his respiration is easily appreciated; the conditions of his

tongue and appetite are indices of the digestive system—of his alvine and urinary evacuations, while his pulse marks the state of his circulation. The history of his disease and the state of his feelings will determine whether his complaint is acute or chronic.

All practical physicians examine the whole functions of the body in a few minutes, and follow a regular method, such as that proposed by M. Chaussier, in his *Tableau de Semeiotique Générale*, which I shall briefly notice. This order consists in examining successively, 1st. the *face* and the differences which it presents, considered altogether, and in particular, of the regions and organs which compose it, such as the forehead, the eyebrows, the eyes, the eyelids, the temples, the cheeks, the ears, the nose, the mouth, the lips, the chin; 2nd. the *attitude* of the patient in bed, if he is obliged to rest in the sitting posture, on one side, on his back, abdomen, &c.; 3rd. the *skin*, its colour, spots, eruptions, temperature, and its dependencies, the nails and hair; 4th. the *vital functions*, which comprise the *motility*, the augmentation of which is manifested by tension, erethism, contraction, tonic or atonic spasms, general or partial; the *diminution* by lassitude, prostration, paralysis; the *irregularity* by anxiety, jactation or restlessness, cramps, subsultus tendinum, or starting of the tendons, carphologie, or grasping at imaginary objects, crocidism, or picking at the bed clothes; the *sensibility*, which may be increased or diminished, and characterised by pain, stupor, or apathy; the *caloricity*, or temperature, the diminution of which causes chilliness, rigors, or shiverings, horripilation, trembling of the limbs, chattering of the teeth; the augmentation of which causes a dry, burning, mordicant heat; the *sleep*, which may be absent, disturbed, or so profound as to approach stupor or coma; the *circulation*, which indicates the action of the heart and the different kinds of pulse; the *respiration*, the disorder of which is characterised by dyspnœa, or difficulty of breathing, orthopnœa, or breathing in the sitting posture, oppression, suffocation, cough, hiccup, and the other phenomena discoverable by auscultation, percussion, succussion, and mensuration of the chest; 5th. the *sensorial functions*, which comprise the external senses, and may be increased, or diminished, or enfeebled, as loss of vision, hearing, smell, taste, touch; the *internal senses*, the alteration of which is characterised by difficulty or nullity of perception, confusion of ideas, vacillation of the memory, fallacy of the judgment, whence result different kinds of delirium, stupidity, idiocy, mania, &c.; the *voice*, which may be raucous, or hoarse, obscure, bass, shrill, whispering, moaning; and the speech or articulation, which may be imperfect or suppressed, as in aphonia; the *movements of the extremities* or limbs, as when difficulty and pain render the position fatiguing; locomotion, or walking, vacillating or impossible; 6th. the *nutritive functions*, the order of which

in digestion, to judge of which, we examine successively the teeth, gums, above all the tongue, the state of the abdomen, epigastrium, or pit of the stomach, the umbilicus or navel, the hypochondriac, hypogastric and inguinal regions, which include the whole anterior surface of the abdomen; and next consider the state of the appetite, thirst, depraved taste, mastication, deglutition or swallowing, if there be indigestion, acid, alkaline insipid vomiting, flatuosities or flatulence, borborygmi, rumbling in the abdomen, &c.; the secretions and excretions, which may be augmented, diminished, suppressed, or depraved, among which we are to observe the cutaneous perspiration, the urine and its quantity, its appearance, sediment, its frequent or rare, difficult, painful, involuntary, or no ejection; the alvine excretions more or less abundant, their vitiated conditions, the saliva, expectoration, and the nasal, pulmonic, uterine, intestinal, and hæmorrhoidal hæmorrhages; *nutrition*, the derangement of which rapidly produces emaciation, or local engorgements, exuberances, changes of tissue, &c.; the *absorption*, which may be augmented, diminished, or suppressed, whence result swellings, œdema, or atrophy of parts; 7th. the *genital functions*, whose powers may be increased or diminished; and the physician will terminate his examination by considering individual circumstances, as the age, sex, constitution, stature, volume, conformation of the body, regimen, morals, passions, education and mode of life, or habitual occupation; while he also attends to habitation, climate, season, and constitution of the atmosphere. It is by the comparison and analysis of these various circumstances that we can arrive at a correct conclusion on the nature of disease.

In acute complaints our object is to ascertain speedily the nature of the malady; but in chronic cases we should inquire into the previous history of the patient, and of the diseases of his immediate relations.

We should next ascertain the physiological and pathological conditions of the patient at the different periods of life; and pay particular attention to the septenary divisions of the ancients, such as infancy, puberty, adult age, and senescence; and learn the state of the functions during the different eras, and also the disorders and diseases from which the patient suffered, as eruptions on the scalp, cerebral affections, glandular tumours in the neck, groins, or abdomen; eruptive diseases, as measles, small-pox, scarlatina, hooping-cough, &c., during childhood; pulmonic affections, as catarrh, hæmoptysis or spitting of blood, disorders and diseases of the organs in the chest and abdomen, are to be suspected after the age of puberty.

A great degree of importance was attached by the ancients to the septenary periods, especially by the Egyptians and Pythagoreans, and we find them noticed by the illustrious Shakspeare. It was held that the age of man

was comprized in seven decades of revolutions of the earth round the sun; and that the life of man consists of hours, days, and years, and his health is influenced by seasons.

Hippocrates ascribed much power to lunar influence. The synodical or mean period of lunation is four times seven, or twenty-eight days; and the father of medicine divided the period of seven into two of three days and a half each, which he considered as influential over disease, whether for better or worse. Hence the origin of critical days. In the early ages very little was done in the commencement of diseases; and it was, therefore, much easier than it is at present, when active remedies are employed, to form an opinion upon crises.

The periodicity of disorders is known to every observant practitioner. The recurrence of the paroxysms of intermittent fevers, and of neuralgia in different parts of the body, is known to every one engaged in practice. Menstruation recurs every twenty-eighth day, or one lunar month, and ten times this period is the term of utero-gestation.

We have this fact upon unquestionable authority, as appears by the words of Solomon: "In my mother's womb was I fashioned to be flesh in the time of ten months." It is certain, however, that the duration of pregnancy may vary; but it is worthy of notice that the lunar period of twenty-eight days is made up by adding the units of the number seven: 1, 2, 3, 4, 5, 6, 7—28. Kirkland mentions a curious fact in support of the diurnal or lunar influence upon the human body. He states that a clergyman in Gloucestershire of his acquaintance, was able to predict the time of parturition with astonishing accuracy, and was consulted very much on the subject. Nurses very often assert that if the process of labour commences at a certain hour in the morning, it may extend to the same hour in the evening, or a little later; and this is sometimes the case. There are many curious statements in Balfour's work on sol-lunar influence; and the following extract from the celebrated Stahl, though evidently liable to exceptions, may be cited:—

"A seven months' child will live. If a child breathe freely the seventh hour after birth, it will survive. On the seventh day the remains of the navel-string drop off. At twice seven days, the infant notices the light; at thrice seven notices objects; at seven months the teeth begin to appear; at twice seven months the child begins to walk; at thrice seven months it begins to articulate; at four times the period it walks alone; at seven years the teeth are renewed; at twice seven years the beard appears; at thrice the period the body acquires its growth; at four times seven years life is in perfection, and continues so until five times seven years; at six times seven years the strength and health begin to fail; at seven times seven the mind has attained maturity; and ten times seven years is the

full age of man, after which period life in general is only trouble and vexation." Blumenbach observes that a large proportion of aged persons die at 84—12 × 7.

Though we cannot subscribe to the foregoing doctrine, we must admit that the development of both body and mind is progressive, and that the seasons have great influence on both. The difference of our moral and physical states in gloomy and fine weather are known to every one.

It is by the former inquiries that we can learn the peculiar disposition and constitution of our patient, and his predisposition or liability to certain diseases. Great attention has been paid to the constitution from the earliest period, as every one knows that recovery will more speedily happen when this is good, than when it is debilitated or injured.

The temperaments must also be duly considered. These are divided into the sanguineous, nervous, lymphatic, melancholic, or bilious, and, according to some, the muscular, or athletic, and genital.

The vascular or circulatory system, predominates in those of a sanguineous temperament: the pulse is strong, the blood is vigorously circulated to all parts of the body, all organs are well nourished, perform their functions well, and hence the health is good, the body is symmetrical, and the mental powers are highly developed. Persons of this temperament will suffer most severely from fevers and inflammations, and will require copious blood-letting, free purgation, and all remedies of a depressing character; in a word, the most powerful treatment, such as could not be borne with safety by melancholic or nervous persons. The knowledge, therefore, of the prevailing temperaments enables us to form a correct notion of the predisposition to disease, and also of the indications of treatment. It would be foreign to my present purpose to dilate upon the temperaments and their modifications, as these are fully described in works on physiology; but I may observe that it is often difficult to distinguish them as defined, on account of difference of constitution caused by marriage.

In our examination of diseases, we must attend to idiosyncrasies, or peculiarities of constitution. We observe the greatest difference in this respect, which will explain peculiar symptoms, and modify our treatment. From the preceding statements it is manifest, that in investigating the nature of disease, we pass in review all organs and functions in the body, compare their natural and disordered or diseased conditions, consider them in reference to age, sex, constitution, temperament, idiosyncrasy, habit, occupation, climate, season, aliment, drink, exercise, passions, and habitual diseases; and, finally, employ those remedies which control, arrest, or remove the varied deviations from health. We are much assisted by the definitions of diseases laid down by systematic authors on the practice of me-

dicine. The first and grand question which every physician should determine in investigating illness is, what is the disease; is it disorder of function only, is it inflammation or its consequences, is it a complication of both? and his conclusion will determine the treatment, which must vary according to the nature of the malady. In simple disorder of function, indicated by *occasional* pain, spasm, or convulsions, we advise sedatives; while in those cases which are characterised by fever and *constant* pain, depletion and antiphlogistic remedies are indispensable. Though this is a received opinion, it is necessary to observe that disorders and diseases are, in general, so complicated, that it often happens, we are unable to determine which form is really the cause of suffering. But in general a correct opinion is formed, after having considered every symptom, however trivial.

Such is the plan of ascertaining the nature of disease both in private and hospital practice. During acute diseases, it is highly improper for students to annoy the afflicted sufferers, by repeatedly asking the same questions. This conduct is generally and properly prevented in hospitals, and was severely and justly censured by Martial:—

Languebam; sed tu comitatus protinus ad me
Venisti centum, Symmache, discipulis.
Centum me tetigere manus, Aquilone gelatæ
Non habui febrem, Symmache, nunc habeo.

It is necessary in all cases to compare the physiological, or natural, and the pathological, or morbid states of the organs and their functions, to determine their alterations, and to form an accurate diagnosis. An experienced and scientific physician can, in many cases, discover the nature of the disease without a single interrogation, and this tact is of vast importance in infantile complaints. The celebrated Stoh was in the habit of discovering the trades of his patients, and veterinary surgeons arrive at their conclusions by the sense of vision alone. If children are able to speak, we cannot depend on their answers, when questioned about their feelings during disease. Again, many adults mislead us by substituting their ideas and fears for their sensations; for example, they say they are feverish, have inward fever or inflammation, without the slightest correct notion of the nature or symptoms of these diseases. Again, some persons conceal their symptoms, others exaggerate them; but we can seldom be deceived, when we take physiology and pathology as our guides.

In our diagnosis of diseases we employ all our senses. Vision enables us to judge of the habit and constitution, of the form, colour, size, and movements of different parts. The countenance and attitude of the sick claim especial attention in our discrimination of the nature and result of disease. The supine position, for instance, is characteristic of profound debility or prostration of strength, as we

observe at the approach of death, and also in inflammations of the abdominal viscera, or in gastro-cephalitic cases, when the organs in the head and abdomen are simultaneously affected. When the patient lies on his abdomen, he labours under colic, or intestinal pains, without inflammation. He reposes on the affected side in many diseases—in dropsy of the chest, inflammation of the lungs, liver, &c.

The changes in the colour of the skin are remarkable in diseases: the skin is a pale yellow in chronic liver complaint; in painters' colic, of a greenish yellow; in chlorosis, white; in anasarca, lepra, or after severe hæmorrhage, of a pale yellow; a leaden colour in cancer; brown or blackish in purpura; blue in malignant cholera. The physiognomy enables us to detect a great number of diseases.

When there is a determination of blood to the head, as in cerebral congestion, incipient hydrocephalus, apoplexy, fevers, eruptive diseases, small-pox, scarlatina, measles, bleeding from the nose, and on an access of mania or hydrophobia, or delirium, the face is red, swollen, and sometimes livid; in consumption, the eyes are brilliant, the cheek bones prominent and covered by a red patch, the cheeks are thin and closely approaching the teeth; in inflammation of the lung, pleura, or liver, the side of the face which corresponds to that of the organ affected, is often red; and the face is red or livid in aneurism or hypertrophy of the heart. The countenance is distressed in cholera, colic, inflammation of the bowels, and all painful diseases; is contorted in convulsions; and the features are changed and sharpened (*facies Hippocratica*) at the approach of death.

The different parts of the face, taken separately, present diagnostic signs. Of these, the eyes are the most expressive of the morbid condition. They indicate the secrets of the mind and body, as well observed by Hippocrates:—"Ut oculi valent, sic ipsa persona." The numerous communications between the branches of the fifth pair of nerves which preside over vision, and the great sympathetic, so admirably illustrated by Sir Charles Bell, whose office it is to transmit to the brain all visceral sensations, convey to the eyes all the morbid changes of the internal organs. It would be easy to offer an immense number of proofs of the validity of this conclusion. In forming a diagnosis, we examine the external and internal parts of the eye, the colour, state of the pupil, and the motion of the organ. The eye is suffused or red in affections of the brain, as apoplexy, incipient hydrocephalus, in fevers, in exanthemata, as measles, small-pox, and scarlatina; the sclerotic coat is of a pearly white colour in consumption, bluish in scrofula, yellowish in jaundice or chronic liver disease. The pupil may be dilated, contracted, or closed, and movable or immovable. The globe of the eye may be fixed or immovable in apoplexy, compression of the brain, from whatever cause, depression of bone, congestion,

hydrocephalus, in amaurosis, during narcotism and catalepsy; or agitated by oscillatory or rotatory motions, in strabismus or squinting, hysteria, epilepsy, and convulsive affections. The eyes are turned up during sleep in ventricular arachnitis, in the last stages of various diseases, or at the approach, or in the agonies, of death.

The eyelids, eyelashes, and eyebrows, afford signs of diseases. The eyebrows are elevated in all the agreeable passions, as joy, astonishment, pleasure; are depressed in grief and anger; and are contracted in painful and convulsive diseases, as inflammation of the iris, retina, and globe of the eye. The eyelids are agitated in epilepsy, mania, hysteria, and in many diseases in which the eye is acutely sensitive to impressions of light; they are depressed in apoplexy, congestion of the brain, effusion (hydrocephalus), and paralysis. It is held by some observers, that the eyelashes are elongated in those predisposed to scrofula and consumption; but this is not always the case; they fall off in several cutaneous diseases, as certain kinds of ringworm, &c.

The tears are effused on the cheek in many complaints—in catarrh, influenza, in obstruction of the nasal ducts, in coryza or cold in the head, in measles, small-pox, scarlatina, in hysteria, dyspepsia, and hypochondriasis, and at the approach of death.

The sense of taste is affected in various diseases. It may be depraved in different degrees, or entirely absent.

The condition of the tongue is indicative of health or disease. This organ has a strong sympathy with the stomach on account of its mucous or external membrane, which is continuous throughout the whole digestive tube, as a part of the digestive apparatus, and as being intimately connected with the stomach by the pneumo-gastric, par vagum, or eighth pair of nerves. Hence we observe its dryness, humidity, colour, size, and motions. It is dry, contracted, and retracted, in the last stages of typhus, inflammations of the organs in the head, chest, abdomen, and all parts of the body. It is humid, soft, and pale, in all diseases of debility, in scrofula, dropsy, delirium tremens, or that peculiar mental aberration, with tremors of the upper and lower extremities, consequent on inebriety.

Its colour is white in the last disorder, in irritation or pain in the stomach and bowels, or in the digestive organs, in the different kinds of palsy, asthenia, and in many chronic diseases; but the tongue does not invariably sympathise with the digestive organs. This colour is characteristic of inflammation of the mucous follicles of the digestive organs, stomach, bowels, &c., and may become grayish, yellowish, brownish, or blackish, according to the severity of the disease. It is now an established axiom that the tongue may become dry, brown, or black during the progress of external as well as internal disease.

—ds. fractures, febrile erup-

tions, measles, small pox, scarlatina, or acute diseases in the head, chest, abdomen, and pelvis. In speaking of all these diseases it is a common remark to say, that typhoid symptoms have supervened, and that the conditions of the tongue just noticed are frequently observed. This fact has led some to contend that typhus is not always an idiopathic disease, but is often symptomatic of local affections.

The tongue is generally red in gastritis or inflammation of the stomach, in scarlatina, measles, and small pox, and in most fevers. When it becomes black, there is most acute and fatal inflammation present, though recovery may happen. It may be affected with aphthous, venereal, and scorbutic ulcerations. The tongue is white on the sides and yellowish in the centre in dyspepsia, and its coats or furs may be modified, according as the individual sleeps with his mouth closed or open. It is swelled in many diseases, as cancer, after the use of mercury, in aphthæ or thrush, in small pox, &c. At the approach of death the patient cannot protrude the tongue beyond the teeth; and this happens in affections of the brain, apoplexy, cerebral congestion, effusion into the ventricles of the brain (hydrocephalus), congestion caused by the sudden appearance of eruptive fevers, scarlatina, measles, small pox, &c.

The signs of disease which are furnished by the external ear are relative to its form and secretions. The ear may be red or livid in organic diseases of the heart or large blood vessels, in all cases in which the respiration is impeded, and in which there is determination of blood to the brain, such as those mentioned in the description of the signs afforded by the countenance. The secretion of wax may be augmented, altered, or diminished in acute or chronic inflammation of the mucous membrane of the ear. There may be a copious, fetid, purulent discharge from the ear, induced by cold, fevers, as typhus, scarlatina, &c.

The sense of hearing may be diminished in compression or congestion of the brain during the progress of fevers and various diseases. M. Broussais considers smallness of the lobe of the ear as a sign of scrofula; and M. Jolly observes that the cretins of Valais offer this disposition very generally.

The size of the nose is increased in coryza, or cold in the head, in scrofulous and scorbutic diseases, in elephantiasis, and with many intemperate persons. It is diminished in size, and is sharpened in nervous disorders, in chronic diseases, and especially in consumption. It is red in all diseases of the head which are characterised by increased vascular action, in coryza, acne, &c.; it is pale or livid in the cold stage of ague and in typhus fevers. A child picks its nose when it suffers from irritation, inflammation, or ulceration of the bowels, and when it is irritated by the presence of worms in the rectum.

The rapid and convulsive motions of the nostrils indicate laborious respiration, as in inflammation of the respiratory organs, typhus, small-pox, measles, scarlatina, and at the approach of death.

The examination of the lips and gums is highly important in the discrimination of diseases. The different parts of the mouth are lined by mucous membrane, which is continued into the lungs and digestive organs, and hence we find these indicative of pulmonary and gastro-enteric inflammations. Thus the lips are red and dry in most of the pulmonary or abdominal inflammations; they are pale in dropsies after severe hæmorrhage; they are blue in cold stages of common, continued, and intermittent fevers, in asthma, in aneurism of the heart or large vessels; and they become livid or black in apoplexy, cerebral congestion, asphyxia from strangulation, suffocation, submersion, or drowning. The lips are parched, and covered with a dark or black fur (*sordes*), in the last stages of typhus and other fevers, as the eruptive, infantile, remittent, &c.; they are covered with an eruption after exposure to cold, in syphilis and cutaneous diseases; they are ulcerated in scrofula, syphilis, and scurvy; they become tremulous on the approach of vomiting, diarrhoea, delirium, epilepsy, hysteria, convulsions, delirium tremens, &c., and they are separated in convulsions, from compression of the brain, which we often observe in cases of children.

The gums are pale in chlorosis, dropsy, scrofula, anemia, after profuse hæmorrhage; they are red in inflammation of the digestive organs, scarlatina, and dentition; they are swollen, spongy, bloody, and exhale a fœtid odour, in scurvy, purpura hæmorrhagica, and sometimes in the last stage of typhus.

The teeth are remarkably white in consumption, yellow in dyspepsia, derangement or disease of the liver or kidney, become carious during pregnancy and indigestion, are covered with a brown or black *sordes* in typhus and low fevers, and also in gastro-intestinal inflammations.

After having examined the different parts of the face and mouth, we proceed to inspect the neck, chest, abdomen, and extremities; and we employ all our senses of vision, audition, gustation, olfaction, and palpation, in our investigations. When the neck is short and thick, it is a sign of an apoplectic tendency; a long thin neck, with high shoulders and a flattened chest, indicate a predisposition to pulmonary disease; and the veins of the neck are distended in certain diseases of the heart or great vessels.

The examination of the surface of the chest affords the explication of an immense number of diseases in the lungs and heart; and this is made by auscultation, percussion, succussion, and mensuration.

The condition of the abdomen will enable us to discover hernia, and many diseases of

the viscera contained in it, as enlargement of the liver, spleen, intestines, &c.

The spinal column will be affected in numerous disorders of the viscera of the chest and abdomen, an admirable illustration of which I lately witnessed in a case, with my friend Mr. Mason, of Newington.

The external genitals will be infiltrated with serum in dropsies; the retraction of one or both testes indicates disease in the kidney, ureter, or bladder; there are painful erections in blennorrhagia, disease of the prostate gland, stricture of the urethra, irritation of the cerebellum, in hydrophobia, epilepsy; there is pain in the glans penis in stone in the bladder, and itching in this part when gastric or intestinal irritation exists in children.

The extremities or limbs are altered in size, colour, in the power of motion. The inferior ones are swollen, or œdematous, in dropsies, enlargement of the liver or spleen, in diseases of the valves of the heart, and in fact in all diseases in which there is an obstruction to the free circulation of the blood through the veins.

As soon as we have concluded this general examination, we proceed to notice the secretions and excretions.

We examine the state of the skin to ascertain the degree of temperature, whether it is dry or moist, or the perspiration is general or partial; we observe lachrymation, or flow of tears, in coryza (cold in the head), in measles, in the different sore throats, or quinsies, hysteria, hypochondriasis, if the nasal mucus is increased or diminished in quantity. We know that salivation, or ptyalism, may be produced by mercury, may precede epilepsy, or be present in indigestion, small-pox, dentition, &c.

The sputa, or expectoration, presents various modifications, is mucous in catarrh, tenacious in bronchitis, sanguinolent in hæmoptysis or spitting of blood, greenish, grayish, or puriform, in chronic catarrh, or bronchitis, purulent in consumption, and black and extremely fetid in gangrene of the lung.

The matters ejected by vomiting afford signs of disease, and enable us to discover the cause in many cases. When blood is vomited, mixed with alimentary matter, the disease is termed hæmatemesis; when a large quantity of limpid fluid, like water, of an acid, saltish, or insipid taste, pyrosis or water-brash is present; and in certain obstructions of the intestines, as strangulated hernia, ileus, &c., faecal matter has been vomited. In yellow fever a black fluid is ejected, in chronic dyspepsia, in cancer of the stomach, a dark matter, like coffee grounds, may be vomited, and in abscess of the liver or stomach, purulent matter may be discharged from the stomach.

In injuries of the head and chronic diseases of the brain, and also in the early months of pregnancy, there may be frequent or even constant vomiting for a few hours or even

weeks. I lately attended a lady, with Mr. Matthews, of Bermondsey-street, who was in her first pregnancy, who vomited every thing taken into the stomach for more than a month, in defiance to all remedies, and I have repeatedly met with cases nearly similar.

The alvine evacuations afford signs of disease. They may vary in quantity, consistence, and colour, and should be examined and described by the patient in chronic diseases, and inspected daily in all acute cases. The healthful colour of the feces is a dark yellow, similar to wetted rhubarb, and a light yellow in children. Any difference in colour is a proof of disease. The feces are dark in chronic disease of the liver, in many of the forms of indigestion, hypochondriasis, and mælena; white in jaundice; liquid, mucous, and sanguinolent in dysentery; they are solidified and flattened in stricture, or narrowing of the rectum, and in enlargement of the prostate gland; purulent in ulceration of the intestine; green, brown, or black, in certain diseases of children, and sometimes containing fatty matter.

The condition of the urine must also be examined; the quantity is in an inverse proportion to that of the perspiration. When it is diminished, the watery or serous part of the blood is deposited in other tissues, unless carried off by the skin or lungs. When the urine is diminished in scarlatina, anasarca soon occurs, and in pleurisy or peritonitis there will be effusion into the chest or abdomen, causing hydrothorax and ascites. The urine may be high coloured, dark, black, white, yellow, red, or mixed with blood, and deposit various sediments, which afford signs of disease. It may be very much diminished, or entirely suppressed, or increased to several pints daily, as in diabetes.

The function of menstruation is liable to much derangement, and must be always attended to when the other sex are the subjects of disease. The sense of vision is often assisted in the detection of diseases by microscopes, speculums, &c.; and that of hearing by the stethoscope, percussion, and succussion, or shaking the body: the sense of touch is of immense value in investigating diseases. The application of the hand enables us to judge of the augmentation or diminution of the structure of many organs, of the changes of configuration and variations of temperature. Pressure on the abdomen will afford us evidence of inflammation in the stomach, liver, spleen, bowels, womb, &c., while by palpation, or gentle percussion, we discover fluctuation in dropsies, in abscesses, and, by pressure with the finger, we make a depression, or pit, in dropsy of the limbs, and hence the term pitting on pressure, which is a positive sign of dropsy. Touch co-operates with other means to enable us to detect pregnancy and fix its date, the progress of parturition, and the presence of various diseases, tumours, polypi, cancer, &c.; stricture and other diseases of the rectum, stone in the bladder, en-

largement of the prostate gland, hernia, stricture of the urethra, œsophagus, lachrymal, and aural passages. The hand applied to different parts of the body facilitates our discerning of the temperature, and with it we feel the pulse, that valuable diagnostic in a vast number of diseases, but not to be relied on in cases of children. The heat varies very considerably; some persons complain of icy coldness when the temperature is much higher than natural. The heat is acrid and mordant in typhus and other low fevers; while a general sense of coldness, preceded by rigors, or shivering, in acute diseases, causes an internal heat, which is characteristic of congestion of the deep-seated organs, and often of inflammation.

The sense of smell elucidates the diagnosis of diseases. Every age, sex, temperament, people, season, passion, aliment, and occupation impresses on the animal economy a peculiar odour. The odour of the excretions is acid in infants, sometimes like that of milk, sweetish and amniotic in woman, and more or less seminal in man. All the secretions may acquire accidental odours from certain aliments or drinks, as from truffles, garlic, asparagus, alcohol, opium, prussic acid, &c., which may be perceived in the perspiration, urine, expired air, &c.; the axillary, inguinal transpiration, that of the feet and of the head, have an odour more or less fetid in the adult, from which the infant and old man are exempt. The acid odour is perceived in miliary and eruptive fevers, in scrofula, syphilis; the fetidity of the breath is an indication of *œzœna*, scurvy, mercurial salivation, carious teeth, and the odour of a mouse sometimes supervenes on low fevers, mania, and epilepsy. The cutaneous diseases have their peculiar odours, as in small pox, porrigo, &c.; so also menstrual and lochial discharges. The cadaverous odour of the expired air or breath, and of the alvine and urinary discharges, afford evidence of disease. The signs afforded by the sense of smell, I have condensed from M. Jolly's article on Diagnosis in the *Dict. de Med. et Chir. Prat.*

The sense of taste is seldom employed at present in the diagnosis of disease. The sweet taste of the urine is characteristic of one species of diabetes. The physicians of antiquity, according to Alexander of Trallia, explored the tastes of the different excretions. He states that they tasted successively the gastric, bronchial, alvine, and urinary excretions. Few practitioners of our times carry their zeal so far as to explore the different morbid products in this manner.

When we have examined the whole functions of the body, as now described, we next proceed to interrogate the patient; and the mode which you have seen me pursue at St. John's Hospital is worthy of your adoption. The history of each case is taken down very minutely in the following manner:—I inquire the name, age, residence, occupation, habits, state of general health, hereditary and former dis-

eases; attend to the age and sex, whether the patient is married or single, the temperament, idiosyncrasy, the nature of the present illness, the situation of pain—whether this is continued or intermittent, deep-seated or superficial, acute or slight, fixed or movable; and, after examining the brain and nervous system, the intellectual faculties, locomotive powers, the senses, the digestive, circulatory, respiratory, secretory, nutritive, and generative systems, together with the condition of the excretions, after a careful review of the principles of pathology, determine the important question, what is the disorder or disease?

In cases of children we must leave no part of the external surface of the body unexamined; and by attending to the symptomatology and pathology of adults, we can, in almost every instance, arrive at a correct conclusion as to the nature of disease.

I have now enumerated some of the signs or diagnostics of diseases, because, until very lately, there was little attention paid to the subject in elementary works upon the practice of medicine; and the special diagnosis given of individual diseases is much too short for the information of medical students and junior practitioners. There are, however, some recent publications which treat largely on this branch of science: such as Dr. Marshall Hall's on Diagnosis; his article, Symptomatology, in the *Cyclopædia of Practical Medicine*; Professor Quain's Translation of M. Martinet's Pathology; Dr. Hooper's Physician's Vademecum; Dr. Armstrong's Lectures on the Practice of Medicine (just published); the *Dictionnaire de Médecine et Chirurgie Pratique*, 1831, art. DIAGNOSTIC; *Dictionnaire du Diagnostic*, par M. Helian, 1771; *Treatise on the Diagnosis and Prognosis of Diseases*, by P. S. Price, 1792; *Semeiotique, ou Traité des Signes des Maladies*, par Landre-Beauvais, 1808; *Semeiologie Générale*, par F.G. Double, 1811—1822; *Symptomatology*, by A. P. Buchan, M.D., 1824; Dr. Forbes's Translation of M. Laennec's *Treatise on Auscultation*; Dr. Ryland's Translation of Collin's work on the different Modes of Exploring the Chest; Rucco on the Pulse, &c.

ESSAY ON THE STRUCTURE AND FUNCTIONS OF THE SKIN.

BY M.M. BRESCHET ET ROUSSEL DE VAUZEME.

Read by the former to the Académie Royale des Sciences, on their sitting, 27th of Jan., 1834.

Rerum natura sacra sua non simul tradit aliud hæc ætas aliud quæ non subibit, adspiciet.
—*Senæger Nat. Quest.*, lib. viii. c. cxxxv, xxxi.

SEVERAL memoirs, which have been presented by me to this Academy, on the structure of

the auditory apparatus, considered in the different families of the vertebrated animals, memoirs upon which reports have been made by M. Cuvier et M. Dumeril, have shown that I was making persevering researches on the organs of sense. It is to complete these labours that I have undertaken to examine the anatomical composition of the skin. As I am deprived of zoological collections, I often find it difficult to provide the means of making dissections. A young physician, M. Roussel de Vauzème, zealous in forwarding natural history, had undertaken for the interests of this science, a voyage on board a whaler. Amongst the products of his tour, he had collected a vast number of cutaneous tissues, the spoils of the cetaceous tribe, and principally of the *Balæna Mysticetus*. I thought this an excellent opportunity of investigating the structure of the skin, and I immediately undertook this study with M. Roussel de Vauzème; we combined our zeal and efforts in drawing up the note which I now present, and which being merely the analysis of the first part of our researches, should be considered as belonging to M. de Vauzème and myself in common. When we compare what science possesses on the structure and disposition of the various apparatus of vision, audition, motion, and sanguineous circulation, &c., with what we know on the anatomical composition of the skin, it is evident that every thing remains to be done on this important anatomical and physiological subject. From *Malpigia* down to our times, it has been thought sufficient to distinguish in the integumentary envelopes, the dermis, the papillary body, the mucous body, the epidermis, and its appendages; but the intimate structure of each of these parts has not been rigorously defined, and generally hypotheses have been substituted for strict anatomical observations. Thanks to the fortunate circumstances which have favoured us, we have been able to discover dispositions till then unknown, or simply in part unfolded. These dispositions having been once recognised in cetaceous and other large mamiferous animals, we have obtained easily a sight of them on man, and on the greater number of the vertebrated tribes.

The principal parts of the skin that we wish to bring before the attention of the Academy, are, first, the dermis; secondly, the nervous

papillæ; thirdly, the apparatus for the secretion of perspiration, composed of a glandulous parenchyma, and of the sudoriferous or hydrophorous canals; fourthly, the apparatus for inhalation, or the absorbent ducts; fifthly, the organs producing horny matter, or the *keratogenous* apparatus; sixthly, the organs producing colouring matter, or the *chromatogenous* apparatus.

1st. *The Dermis*.—Its form is that of a membrane stretched over the whole surface of the body; its internal surface is formed by a rough interlacement of lamellæ, or of fibrous filaments, which gradually become more dense towards the external surface, and finally constitute a firm and solid plane. The dermis is perforated by a great number of openings, some of which give passage to nervous filaments, others to small glandular organs, whose excretory duct passes through the thickness of the dermis to open on the external surface.

A great number of adipose vesicles may be observed to unite in bunches around the globules we have just mentioned. Lastly, it is penetrated by an infinity of lymphatic vessels. On its external surface the dermis seems to blend itself with the parenchyma of the organs which secrete the colouring matter, and with the papillary tissue. The dermis, according to us, is nothing more than a fibrous canvas, traversed by organs of a very different nature.

2nd. *The Nervous Apparatus of the Skin and Papillary Bodies*.—It is known that the nervous filaments proceeding from the various trunks, dispersed in different directions throughout the cellular tissue, ramify and subdivide to infinity on approaching the cutis. It is possible with perseverance to follow them as far as this membrane, where they are in general lost, on account of their tenuity, or the opacity of the tissues.

It would be impossible to distinguish nervous filaments amidst the vascular interlacement of the cutis, if the points at which they emerge were not visible. In fact, it is discovered, that on approaching the surface of the cutis, bundles of nervous filaments become slender; and, as if very pulpy, direct themselves towards, and finally penetrate, the base of the papillæ.

The papillæ are arranged in a continuous series; their form is that of a cone, whose base extends into the cutis, and the summit.

terminates in a rounded point. Each prolongation penetrates into the horny substance constituting the epidermis and corpus mucosum, as a sword is received into its sheath; it is this which causes the internal surface of the former to represent the exact number and arrangement of the papillæ by its symmetrical depressions. On separating these two portions of skin, the epidermis is readily removed, but the papillæ always remain firmly adherent to the cutis by their base. The direction of the papillæ in the horny layer constituting the epidermis is slightly oblique. The horny substance furnishes a proper sheath, which covers them with a hood-like investment, in addition to the neurilema which they receive from the cutis. These papillæ sprout from the cutis in innumerable quantities; thus the horny tissue is as pierced as a sieve.

In the skin of the whale, the papillæ are several lines in length, present an enlarged base and summit, which terminate in an olivary eminence. They terminate not far from the superficies in a slight inclination, after having traversed nearly the entire thickness of the horny tissue of the epidermis. Their external appearance presents a pearly and opaque whiteness. On examination by means of a powerful lens, the nerve presents through the neurilema undulated striæ, which proceed from the base of each papillæ, where they are very distinct, and become less marked in proportion as they approach the terminal expansion, where they form concentric arches or loops. Not the slightest vestige of any filament, of any prolongation proceeding from the summit of these papillæ to communicate with the adjacent tissues, can be detected.

The mode in which the nerves that arrive at the cutaneous tissue, in order to constitute the papillæ, terminate, is exceedingly curious.

The papillæ, studied, in the first place, on the whale, where they offer the highest degree of development, and afterwards examined on the human skin, where their tenuity does not permit their just perception, present the same arrangement and the same structure. Before we commenced our experiments, the mode in which the filaments which constitute the papillæ terminate was unknown, and the nervous endowment of these organs still contested, since Gaultier considered them as essentially vascular.

The final termination of the nerves still remained to be ascertained, and science presented only to inquiring genius observations, presumptions, and hypotheses, in place of facts. The diverse opinions which anatomists entertain on this subject, are capable of being classed under three heads.

A.—It is presumed that the nerves lose themselves in the primitive tissue, or woof of these organs, and become identified with their own peculiar substance; hence it is impossible to recognise and appreciate the mode in which the nervous chords terminate.

B.—The nerves, incapable of being distributed throughout every part of the same tissue, and of all organic systems without exception, are surrounded by a peculiar atmosphere, by means of which they extend their action to a certain distance, very nearly in the same manner as the electric fluid is observed to exercise an influence on remote bodies by the force of attraction and repulsion.

C.—The termination by means of arches, has been attributed to nerves, and hence these organs may be compared to a galvanic apparatus. Deeply reflecting and high talented individuals have already signalled this arrangement, as regards the nerves of motion, and my own observations, not only on what appertains to the superficies of the body, but the additional researches that I have made on various other organs, especially the auditory, lend an additional support to the facts already advanced by a member of this Academy. The knowledge of these anatomical conformations, which possess so much physiological importance, will conduct to a more perfect comprehension of the phenomena of motion and sensation. This discovery, however, requires to be verified by multiplied facts; but these observations ought to excite the curiosity of natural philosophers, since they appear to indicate that the laws which govern inert and organised bodies are identical.

3rd. *Of the Apparatus concerned in the Cutaneous Exhalation, or of the sudoriferous and hydrophorous Canals.*—These organs occupy the entire substance of the skin, from the interior of the epidermis as far as the most superficial layer of the epidermis, where it terminates in numerous apertures.

Its composition consists in an organ of secretion and an excretory canal. The organ of

secretion is situated in the substance of the cutis, surrounded by numerous capillaries which penetrate its tissue; its form is that of a small vesicle, from the superior part of which emanates a spheroidal canal, which traverses the cutis and the entire thickness of the horny epidermic layer; and hence proceeds, after having described very spherical circumvolutions, to open itself on the exterior surface of the skin in the projecting lines, which this general envelope presents.

This spiral arrangement of the excretory canals enables them to present an aperture which is exceedingly oblique, and almost parallel to the plane of the cutaneous tissue. Both margins of this aperture become closed by the approximation of the superior and inferior parietes of the tube. On examining, by means of a magnifying glass, the perspiration which transudes from the surface of the skin, it is seen that the exit of the first drop is preceded by an elevation of a point of the epidermis, resembling the action of a valve. The spiral conformation of the sudoriferous, in man, is very curious; it explains the reason why the epidermis, evidently permitting the passage of excreted fluids, has always appeared imperfect. In short, when a piece of integument is removed from the dead or living body, the *hydrophorous tubes*, lacerated by the violence which has been exercised, retract, and thus close the small apertures existing in the epidermis.

(To be continued.)

ON THE OCCURRENCE OF SUPERNUMERARY CERVICAL RIBS IN THE HUMAN BODY.

BY ARCHIBALD DYMCK, M.D.

THE present case occurred in the body of a male, apparently of about twenty-eight years of age, of full growth, and remarkably good proportions, none of the other organs showing any deviation from their normal state. Unfortunately the putrefactive process had advanced so far as to prevent the investigation of the relation of the adjacent soft textures. The present description must therefore be limited to a detail of the appearances presented by the bones themselves*.

* In the *Mémoires présentés à l'Académie des Sciences*, M. Sue remarks, in cases of

On either side of the seventh cervical vertebra is placed an oblong bony process, which is articulated to the former at two points, namely, at the upper and lateral part of the body, and at the external or free extremity of the transverse process. These bony processes run in a curved direction outwards and forwards, immediately above, and almost parallel with, the first pair of true ribs, their course only varying from that of the latter, in so far as it describes a portion of a circle of smaller diameter. Of these bones, that on the left side is the larger, its length being nearly three inches, and that of its fellow being only an inch and a half. Their vertebral extremity possesses more strength and thickness than their anterior; and their body assumes a rounded and slightly twisted form, being almost entirely deprived of that flattened configuration which forms a characteristic feature in the dorsal ribs.

Each of these rudimentary ribs is furnished with a tuberosity and head, which are connected to the *vertebra prominens* exactly in the same manner as the corresponding points of the regular ribs are articulated to their respective dorsal vertebrae, namely, by ligaments and synovial membrane. Betwixt the tuberosity and head there is a prominent line or ridge directed obliquely downwards and outwards; and on the inner side of this is placed a groove, along which the vertebral artery passes before entering the hole in the transverse process of the sixth vertebra of the neck. Anteriorly, these processes terminate rather abruptly, and without any cartilaginous prolongation; that on the left side being somewhat increased in size, and connected to the following rib by a strong fasciculus of tendinous fibres.

The body of the *vertebra prominens* is unusually deep, approximating very closely in point of size to that of the first dorsal; besides which, it presents one complete costal impres-

supernumerary cervical ribs, the chest is rendered more capacious in its vertical diameter; the sacro-lumbar, and other long muscles of the back, have an additional tendon; the large vessels arising from the heart are longer, in consequence of that organ remaining in its natural position, and there are two additional sets of intercostal arteries and muscles,

pion, and a demi-facette on each side. The foramen generally found in its transverse process (and which Meckel affirms never affords passage to more than a branch of the vertebral vein) is here absent, an omission that offers another point of resemblance in addition to those above mentioned, which the seventh cervical vertebra has to the dorsal.

From the preceding facts, I think we can have little difficulty in considering these processes of bone as the rudiments of ribs, no doubt rarely developed to such a magnitude, but not on that account rendering our conclusion less satisfactory or more open to fallacy. Two arguments may be adduced in support of this: first, that precisely similar cases have been recorded; and secondly, that such apparently anomalous cases are not only not inconsistent, but are actually in perfect unison with those laws of organisation which nature follows in the construction of animal bodies.

Most systematic authors on anatomy notice an occasional increase or diminution in the number of the ribs; but there are comparatively few who have met with such deviations themselves, and still fewer who have given anything like a minute account of what fell under their observation. Galen, Columbus, Ruyach, Valverde, Riola, Fallopius, Peccolomini, Winslow, and others, have each seen cases, but have not given the details whether the supernumerary ribs were met with in the cervical or lumbar regions.

M. Hunauld, in the *Mémoires de l'Académie Royale des Sciences* for 1740, has given four delineations, in one of which the additional rib reaches the sternum. Professor Otto, of Breslau, has alluded to the occurrence of ribs in connexion with the seventh cervical vertebra; and mentions in his *Anatomie Pathologique*, that two specimens are preserved in the Museum there. He saw a third in the Museum at Christiania in the skeleton of an adult; on one side the rib extended as far as the breast-bone, on the other only to the middle of the first true rib. He likewise notices a fourth case in the collection of the Josephine Academy at Vienna. In the *Deutsch. Archiv. für die Physiologie*, Meckel records another example, which is chiefly remarkable from a synovial apparatus at its anterior extremity. These cases are amply sufficient to explain that such ano-

malous developments are not to be found in some merely fortuitous deviation on the part of nature, but must be explained by those uniform and perfect laws which regulate her in the formation of beings.

The organised osteogeny of the cervical vertebrae was first discovered, and afterwards described, by M. Hunauld in the memoir before referred to. It has since been confirmed more particularly by Bechard and Meckel, who have demonstrated that the *vertebra prominens* has invariably two points of ossification, in addition to those met with in the other vertebrae of the neck. They are placed one on each side, in a transverse direction, before the pedicle which connects the lateral processes to the body. They are said to be visible so early as the second month of uterine life, and at the third and half to be a couple of lines in length. Towards the fifth or sixth year, the internal extremity of each horizontal bony nucleus unites itself to the anterior part of the pedicle, and lateral part of the body of the vertebra; the external extremity unites itself simply to the summit of the transverse process.

In cases where rudimentary ribs are formed upon this vertebra, there is no difference whatever in the order or nature of the above phenomena, unless that they are carried on with more activity. The external extremity of the horizontal plate of bone, instead of terminating at the summit of the transverse process, passes beyond it, and there is either a complete cervical rib extending to the sternum, or one more imperfect, which ends at some intermediate point, a variation probably produced and dependent upon the presence or absence of additional intercostal arteries. The supernumerary ribs are seldom exactly alike, there being sometimes only one, and sometimes one more fully developed than its fellow. They have seldom been met with except in connexion with the *vertebra prominens*, a circumstance that might have been anticipated from a knowledge of the preceding facts.

Of the practical importance of these cases, it is unnecessary to speak. In tying the subclavian artery, such a conformation might occasion some embarrassment, but the extreme rarity of such an occurrence renders any further remarks superfluous.—*Edin. Med. Jour.*

Foreign Medicine.

Experiments upon the Créosote, or the Immediate Principle of Tar.

BY M. COSTER.

We find, says the author, in an English work written long back by Berkley, more than five hundred cures obtained by the use of tar water. He stated that if any medicine was entitled to be called a specific it was this. Aware of the exaggerated description of Berkley, and his singular way of explaining the operations of this remedy, M. Coster thinks that still it ought not to be rejected as entirely useless, and expresses his astonishment that a medicine once esteemed so valuable, should have fallen into such complete discredit. For the last year and a half he has employed the tar water in a great number of varied cases, and amongst other diseases, states that nothing has proved of more efficacy during the convalescence of cholera. Soon after the observations upon the créosote by M. Reichenbach (*vide Med. and Surg. Journal, vol. iv., page 732*), M. Coster determined to make trial of it in some cases, and the following is the result of his researches into its merits.

1st. In a case of chronic inflammation of the free border of the eyelids, accompanied in many places with little suppurating ulcers, he touched the parts with an aqueous solution of créosote (made by adding 12 drops of this substance to 2 ounces of water), twice in the day: the disease had existed for many years, but after the application of this solution for ten days, the cure was complete.

2nd. In seven cases of violent toothach, in which the teeth were all carious, the créosote caused the instantaneous cessation of the pain, and arrested the progress of the disease in the teeth.

3rd. An injection of an extremely diluted solution, was made into an abscess of long standing, which communicated with the coxo-femoral articulation, in a young child; at first acute pains were produced, but in the course of an hour they had completed ceased. The remedy was applied daily, and with such decided benefit, that the child, who before could not even move in bed, now sat up, without suffering any pain.

4th. He next employed the créosote in a

young girl affected with lepra. The disease had not only attacked the exterior of the body, which was thereby much altered, but the interior of the mouth was covered with fetid ulcerations, the respiration hoarse, and this girl appeared to be menaced with suffocation; the créosote is now being administered both internally and externally, and appears, as far as the case has hitherto proceeded, to be attended with much benefit.—*Gazette des Hôpitaux.*

Funeral of M. Bennati.

The funeral of M. Bennati took place on the 12th March, in the cemetery of Montmartre. Two orations were delivered on the occasion, one by M. Julia de Fontenelle, in the name of the Physical and Chemical Society of Paris, the other by M. Davet, in the name of his countrymen.

M. Bennati was born in 1798, and was killed by being knocked down in the Boulevards by the runaway horse of a lancer; he lived only twelve hours after the accident. On examination of his body, fracture of the occipital bone and orbital portion of the frontal was found, with considerable effusion of blood.

Chronic Catarrh of the Bladder.

This disease does not always occupy the whole of the internal surface of the bladder, but is often confined to the neck, in which case the patient holds his water pretty well, but the first jet is accompanied by a viscid, mucous matter, analogous to that discharged from the vagina in affections of the internal surface of the neck of the uterus. M. Tanchon speaks highly of a seton applied to the pubes in these cases, attention to diet, with turpentine, and the balsams (especially storax) being at the same time prescribed; these remedies, without the seton, he has found unsuccessful.

On the Mechanism of the Sounds of the Heart.

BY M. MAGENDIE.

The physiological explanation given by Laennec of the sounds of the heart, is founded rather upon deductions drawn from the time and place where they are produced, than from direct observation. The one on the left side, he concluded, arose from the contraction of the ventricles, the other, heard at the lower part of the sternum, from the contraction of the

auricles: as to the immediate cause of the sounds, he attributed them to vibrations of the muscular fibres, at the moment of their contraction. The experiments of Hope prove that the contraction of the auricles precedes the first sound of the heart; that it is followed by no particular sound, and that the second sound coincides with the dilatation of the ventricles. More recently, M. Ronanet has attempted to prove that they were caused by the flow of blood against the valves. All these explanations appeared to M. Magendie unfounded, and he made numerous experiments, which tend to prove that the first sound is owing to the shock of the apex of the heart against the walls of the chest, and that the second arises from the anterior part of the right ventricle, at the moment of its dilatation, striking the sternum and right side of the thorax.

M. Bouilland, however, thinks, that simple and ingenious as the theory of this physiologist may appear, it is not entirely satisfactory. Yet, in presence of an authority as imposing, and of facts as positive, as those related by M. Magendie, we at least must still remain in doubt on the theory which attributed the double sound of the heart to the motion of the valves. M. Bouilland exposed the heart of a vigorous cock, in which he had previously distinctly heard the double sound: he first applied his naked ear, and afterwards the stethoscope, while the heart was yet enveloped by the pericardium, and then after that membrane had been removed, and in both instances the double sound was evident, although there was no contact between the heart and parietes of the chest, particularly between it and the sternum. He perceived a particular sound from the friction of the organ against the stethoscope, but it was very different to the *tic-tac* of the heart. It was removed from the chest, and continued to beat for some moments, either spontaneously or from artificial stimulus, but in this state no sound could be perceived. The same results were obtained by experiments on two rabbits; the sounds were heard distinctly when the heart was no longer in contact with the walls of the chest.

New Composition for Issue Peas.

M. Frigerio has communicated to the Aca-

demy of Medicine a notice of a new kind of issue peas, composed of resin, powdered meze-reon, marshmallow, and orris root, which can be moulded to any size, and made more or less active in their composition, according to circumstances. They excite a more regular and abundant discharge, without causing the pain and inflammation that frequently arises from the swelling of peas made of the root of the iris.

New Method of employing Spirit of Meze-reon.

M. Leroux thinks that the employment of this substance is more easy, and its results quicker and more certain, if the extract is dissolved in a solution of soap and alcohol. A combination which enters the skin more easily is the result. The part is to be rubbed with a flannel, soaked in this liniment; in six or eight hours a number of small pimples appear; but it is necessary to rub the part two or three times, and cover it with flannel. It has been frequently employed with success in acute rheumatism, and some affections of the stomach attended with vomiting, and even in hooping-cough. It is much more active and less painful than the tartarised antimony ointment.

Cancerous Disease of the Bones.

M. Sanson exhibited to the Academy of Medicine the bones of the vertebral column and extremities of a woman who died in the Hôtel Dieu, and which offered a remarkable example of the cancerous diathesis.

The woman, aged 40, was admitted with cancer of the breast; but, as M. Dupuytren thought an operation impracticable, she went out of the hospital, but returned in four or five months in a dying state. Besides the cancer in her breast, she had several tumours in the abdomen. In moving in her bed she broke her thigh; and, in setting this fracture, the femur of the opposite side was broken. On the examination of her body, schirrous tubercles were found in the parietes of the abdomen and lumbar muscles, in the lungs and liver; the heart, spleen, and kidneys were alone free from them. The osseous system was loaded with them: one, the size of a walnut, was found in the structure of the frontal bone. The bodies of most of the

vertebræ, and the cancellous structure of the thigh-bones, contained an enormous quantity: some of them were in a softened state. Where they were most developed the walls of the bones were thin; and in these parts the fractures had occurred.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, March 29th, 1834.

DR. GREGORY in the Chair.

Falsehoods of the Medical Gazette—Dr. Gregory and the one Faculty—Neuralgia—Strychnine—Veratrin.

MR. HUNT rose to call the attention of the meeting to a gross attack made upon the Society in the *Medical Gazette*, which caricatured their proceedings, and contained a tissue of falsehoods from beginning to end. He hoped there was no member of the Society who was capable of writing such an article, and he was willing to suppose the writer wished to play a hoax on the editor of the journal to which he alluded. He proposed that the Secretary should read the article of which he complained, which dramatised the proceedings of the Society.

Dr. James Somerville, Mr. Pettigrew, Mr. Costello, and Mr. Smith objected to the Secretary's reading the article, but called upon the mover to do so.

Mr. Hunt then read the obnoxious and mendacious document; and then observed that it not only insulted the Society at large, but the individual who now filled the chair.

Dr. Gregory felt called upon to explain the part he took in the debates on reform, and denied that he had acted inconsistently. He opposed the eighth resolution, relative to the one faculty, in consequence of the comments made upon it by Dr. Somerville, for he never intended to sanction the fusion, if he might be allowed the term, of the different ranks of the profession into one faculty. He proposed an amendment to the effect of petitioning for a governing body; but he had no idea of sanctioning the destruction of the existing medical corporations. He did not draw up the original resolution with regard to one faculty, and afterwards oppose it, as alleged by Mr. Hunt; and if the original resolution were ex-

punged from the minutes, he would cheerfully sign the petition on the table.

Mr. Hunt felt that his honour and character were now questioned, and he therefore called upon Dr. Somerville, at whose house Dr. Gregory penned the eighth resolution, to state the fact.

Dr. Somerville then stated that Dr. Gregory had penned the resolution, and

A Gentleman emphatically declared that he had copied the eighth resolution from Dr. Gregory's hand-writing for Dr. Johnson.

Dr. Johnson observed that the resolution was drawn up by Dr. Gregory, and did not differ from that inserted in the petition. The words faculty and governing body meant in reality the same thing, and those who thought otherwise, made a distinction without a difference. He thought that the article which gave rise to the present conversation, was too contemptible to deserve serious notice.

Mr. Salmon remarked that Dr. Gregory, in asking to rescind the original resolution, went, in his opinion, much too far, when he imagined the Society would do any such thing for his signature to the petition.

Mr. Costello read the clause in the petition, and commented upon it and the original eighth resolution, which he considered identical. But to remove all doubt, he moved that the minute of the former be read.

A gentleman seconded the motion.

Dr. Somerville hoped Mr. Costello would withdraw his motion, as the whole matter was unworthy of serious consideration.

The subject then dropped, and

Dr. Johnson rose to call the attention of the Society to a matter more congenial to their objects, a history of disease. A clergyman had applied to him since the last meeting, who suffered for two years from tic douloureux of the left eye. The paroxysm was preceded by a tingling sensation in the lips and cheeks, great depression of spirits, and it lasted for ten or twelve hours, when he vomited a greenish fluid; and the disorder immediately ceased. A variety of remedies had been tried without any benefit.

Mr. Costello had known quinine effect a cure in such cases.

Dr. Ryan wished to learn the state of the general health and digestive system of the patient under the care of Dr. Johnson.

Dr. Johnson replied, that both were good; that the patient was forty years of age. The nitrate of silver was the remedy employed at present.

Dr. Ryan would suggest the strychnine; he had found it better than any other remedy. He was happy to be enabled to inform the Society, that a nobleman, whose case was lately noticed, was now free from his neuralgia; but whether from strychnine he could not say, as he heard of the favourable issue from an individual who did not belong to the profession.

Mr. Costello asked was it the case of the Marquis of Anglesey.

Dr. Ryan replied in the affirmative.

Dr. Johnson wished to inquire from the Society, whether any member had tried veratria, as he had found it fail in three cases.

A gentleman said that he had used it in one case, and that it removed the skin of the face. The strength of the ointment he employed was six grains to two drachms of adeps.

Dr. Johnson observed that this was too strong; the proportion he used was ten grains to the ounce.

Mr. Savory related three cases of facial neuralgia relieved by the veratria, but in less quantity than mentioned by the preceding speakers; the proportion of the ointment in common use was six grains to the ounce of adeps. He had prepared at least three prescriptions daily for the last six weeks. One gentleman brought him one in English, ordering an ounce of veratria to the ounce of adeps. He said this was a mistake, and advised him to try the usual ointment, which he did with advantage. A great deal would depend upon the genuineness of the medicine,—the price was very high,—the ounce of ointment could not be had for less than fourteen shillings.

A gentleman mentioned the case of Mr. Day, which was well known to the public. That gentleman had apoplexy, followed by amaurosis and neuralgia in different parts of the body. He used a quarter of a grain of strychnine four times a-day for ten weeks, and was nearly cured of his neuralgia. He would ask Dr. Johnson if he had examined the state of the blood in neuralgic cases?

Dr. Johnson replied in the negative.

The gentleman said that in cases that defied all remedies, he found the blood depraved;

and, by giving medicines to restore it to its normal condition, he succeeded in nearly curing the neuralgia.—Adjourned.

ROYAL COLLEGE OF PHYSICIANS.

On Monday last a meeting was held at the Royal College of Physicians—Sir Henry Hallford in the Chair—and one worse attended has not taken place since the commencement of the season. There were not a dozen eminent individuals present, and the Chair was supported by Dr. Maton and an individual whose name we could not learn. The majority of the meeting consisted of junior members of the profession and students. It is a glaring fact, that the licentiates of the College are not allowed to enter their own hall without a special invitation or leave from the president and fellows, nor to introduce a friend.

Dr. F. Hawkins read a paper by Dr. Williams, of St. Thomas's Hospital, on the Pathology and Treatment of Syphilis, which was elegantly written. The ravages of the disease in the different tissues were illustrated by cases; and the narrator mentioned that he had derived the best results from hydriodate of potass in cases of syphilitic affections of the tendinous sheaths of the fingers.

The conversation turned on Medical Reform, and it was the general opinion that the College monopoly and insolence were at an end.

MEDICAL REFORM.

A public meeting of medical practitioners was held on Tuesday in the Tontine Hotel, Glasgow, for the purpose of expressing their opinions, and to petition Parliament on the subject of Medical Reform. Dr. Andrew Buchanan was chosen chairman. Several excellent speeches were delivered in support of the resolutions, setting forth many of the evils which oppress the profession, and pointing out various remedies, the principal of which consisted in effecting an adequate and uniform curriculum of education in all the medical schools throughout the kingdom, and a thorough revision of the system of licensing. A committee was appointed to draw up a petition to the legislature, embodying the resolutions, which, we understand, is to be forwarded to his grace the Duke of Hamilton, and to Mr. James Oswald, for presentation in the respective Houses of Parliament.

London Medical & Surgical Journal
 Saturday, April 5, 1834.

THE COLLEGE OF PHYSICIANS AND
 THE HOSPITAL LECTURERS.

THE temptation of an increased rent must be considerable when a landlord resolves to pull down a house already tenanted, and build a fairer and more commodious tenement on its site;—as long as brick and mortar will hold together, and keep the premises, to all appearance, wind and water tight, there is a chance in favour of the old building. In the country it may even crumble into dust through all the stages of ruin:—it is easier to build on a new foundation than to clear the old. In a city, however, the public interest interferes: but, until the dilapidated structure is condemned, by public authority, as dangerous to externs as well as interns, and its removal enforced, the greedy landlord has recourse to all manner of shifts and contrivances to

“Patch a wall to expel the winter’s flaw,”

that the unwary tenant may be seduced to inhabit the plastered ruin*.

This passage in the natural history of decayed houses, has its parallel in the history of decayed and rotten Corporations; some have gone to ruin unheeded, while others, of the stamp of the College of Physicians, resort to all the artifices of plaster to hide their slips and flaws, and present a mimic front of fair cut stone, and pillars, and flowered capitals, notwithstanding that the foundations have slipped and the walls are opening. The public architect must interpose; in our

example he has interposed, and the whole building is condemned. *A new structure must be raised.*

Not to pursue the metaphor farther, it is beyond the limits of controversy, that all the medical corporations of the United Kingdom, sixteen, we believe, in number, are at this present moment on their trial to render an account of their deeds; and that it depends upon the resolution of the Parliamentary Committee, which will doubtless be sanctioned by the legislature, to decide what shall be the measure of their power for the future, if any of them shall survive the result. Some must be abolished; others will become co-ordinate schools of medicine for the whole profession, where the science will be taught upon an uniform plan;—other schools will be raised in the metropolis, where the first and best ought to be found. But, after all these arrangements, there remains the task of assigning a head to the members,—of depositing the government of the profession, as a liberal profession worthy above all others of the patronage of the state, in some body alive to its honour, composed of its most distinguished ornaments, zealous to promote and direct medical studies, according to the advanced state of knowledge, and meriting by these qualities the confidence of the humblest individual belonging to the profession. This high office of controlling the whole body of medical practitioners, whether physicians, surgeons, or apothecaries, is now at the disposal of the legislature; and it is characteristic of the College of Physicians,—that Corporation, whose desertion of its proper duties, whose abuse of the powers it has exercised contrary to law, has been most flagrant,—it is a crowning specimen of its effrontery, that, at the very time when its misgovernment and delinquency is about to be presented from the confes-

* Nos urbem colimus tenui tibicine fultam
 Magna parte sui: nam sic labentibus obstat.
 Villicus, et veteris rimæ contextit hiatum
 Securos pendente jubet dormire ruinâ.

stions of its rulers at the bar of the House of Commons, it is using every machination, by its emissaries and underlings, to claim for itself the honourable, the important trust of conferring medical degrees.

So deeply-rooted is the disgust excited by the conduct of that Corporation, that we apprehend, if it were even thoroughly purged of its active instruments—if its President and his whole train were displaced to-morrow, and its laws remodelled upon the justest principles, the very name has become offensive, and would entail mistrust upon any institution, however differently constituted. But, *unless* the whole machinery is altered, *unless* every atom of the old stuff is removed, it would be impossible to satisfy the profession with a governing body bearing such an inauspicious name.

It would not be polite to reveal the whisperings of certain retainers of the College, touching the examination as far as it has gone. Suffice it to say—if it is necessary to say—the confident assurance of these gentry is not warranted by what passes in the Committee Room. We are not at liberty to disclose in print the result of the investigation; but, when the time comes, we shall startle the talkers with a reminiscence of their prophecies.

Some weeks ago we noticed some hole-and-corner proceeding of certain persons, calling themselves the Lecturers of the Great Schools, to wit, the Hospital Lecturers. They—whose conduct and operations are well known, whose influence in lowering professional acquirements in the bulk of practitioners, and in degrading the College of Surgeons to be an instrument of their monopoly is undoubted—are, it is understood, now pressing forward in behalf of the College of Physicians, in humble confidence, if that body acquire the power of conferring the doctorate,

it will not forget to serve its friends in their turn. We have an eye upon these reciprocal kindnesses. Any manœuvres of the kind can be of little avail in obstructing the course of Medical Reform; but they are clear indications of the ruling passion for power and monopoly, strong in the agonies of expiring, and their disclosure serves to put the cautious on their guard against the devices of the enemy.

DR. GREGORY AND THE WESTMINSTER MEDICAL SOCIETY.

WE are not about to resume the whole subject of the Westminster Medical Society affair; but we must refer our readers to the report of the proceedings on Saturday evening last, for a fitting commentary on an article, or two articles, in a late number of the *Medical Gazette*, alluding to the petition to Parliament presented by the Society, which was alleged not to be in accordance with the one faculty resolution. Upon this allegation a superstructure of dramatic abuse was raised by a correspondent in our cotemporary, and a leader was got up to point the malice of the communication. Dr. Gregory exhibited an exemplar of endurance on past occasions, rivalled only by the specimen of obstinate immobility he presented on the late occasion. His adhesion to the Chair indicated a power beyond mere inertia; for every possible effort was unavailing to move him. We recommend the phrenologists to favour us with some remarks upon the organ of sitting, which may perhaps explain the phenomenon.

In truth, and in earnest, it was painful to see a gentleman put himself in such a position. It was plainly the general opinion that the Doctor had written one or both of the articles, in ridicule of the Society over which he so often presides. The practice of that journal in receiving *rankling*

shafts from many quarters, as it openly professed, favours the supposition. Words of very strong import, impeaching the truth of our cotemporary's articles, were hurled at the chair in very unsparing measure. The Doctor should have either disclaimed at once the articles in question, and bastardised them upon some of the "no-ones,"—for no man with a name would indite a falsehood,—or else, right or wrong, he should not persevere in presiding over the body he was supposed to have insulted, and should have stood openly on his defence—we should then commend his spirit at least. No man can pretend not to understand such broad imputations against his fair dealing, as we are sorry to see the Doctor's passive endurance submitted to:—the slightest whisper ought to be enough.

MR. GUTHRIE'S CLAIMS TO THE INVENTION OF URETHRAL INSTRUMENTS.

To the Editors of the London Medical and Surgical Journal.

GENTLEMEN,—Mr. Guthrie, in his Clinical Lecture published in your Journal of the 15th ult., gives an account of an instrument for dilating the urethra, which he speaks of as being his invention. Judge of my surprise, therefore, when, on reading it, I discovered that it was an instrument made by me, slightly modified, at Mr. Guthrie's suggestion, from one wholly my own invention. Mr. Guthrie may suppose that I have only now to resign into his hands the honour of an invention, which, with his characteristic modesty, he has hitherto permitted me to enjoy, and to be grateful for his kind forbearance in having so long granted me this privilege; but I must beg to be allowed permission to prove my claim to the merit of having contrived this instrument, by a plain statement of facts, through the medium of your Journal, which has been made the means of depriving me of the credit of it, and I trust it will have the effect of repairing the injury done to me by Mr. Guthrie, and also to refresh his memory with respect to the point at issue.

In the latter end of the year 1820 Sir A. Cooper called on me, and gave me a drawing of an instrument which he wished to have made for the purpose of extracting small calculi from the bladder of a patient, through the urethra. I made the instrument according to his instructions, but it was found not to answer the purpose. I then said that I thought I could contrive an instrument which would effect the proposed object, by making it to open *in the bladder instead of the urethra*. This, Sir Astley Cooper said, was just what he wanted; I made the instrument, and its success was complete. Sir Astley called on me a few days after, and told me that he had extracted several calculi through the urethra, and among them several large ones, which he had accomplished by opening the instrument while in the urethra, and *dilating it sufficiently to allow of their passage*, but that there still remained many more in the bladder. Soon after this I took Sir Astley another instrument, much more perfect, with which he was so highly pleased that he kept it, and returned me the former one, thanking me for the trouble I had taken *. Some months after Mr. Guthrie suggested to me the idea of an instrument on the same principle, but with three blades instead of two, for the purpose of dilating stricture, which I accordingly made. This is the instrument in question, which Mr. Guthrie calls his. I have always called it "Weiss's Dilator," and no objection was made to the appellation until about five years ago, when Mr. Guthrie called on me, and stated verbally what he has now published. This I disproved, as I thought, to his satisfaction, by producing my workman's book, by which the priority of construction of the two-bladed instrument was manifest. Since then he has never mentioned the subject to me, and I thought he had abandoned the notion of claiming it, until I saw his statement reiterated in your pages.

The reputation of the surgeon in his professional capacity, and of the mechanic in his occupation, is separate and distinct; and it would not really be a greater assumption on the part of the mechanic to arrogate to himself the merit of a successful operation, because he

* An account of this case will be found in the *Medico-Chirurgical Transactions*, Vol. II., page 349.

had made the instrument with which it had been performed, than for the surgeon to lay claim to the credit of the invention of the instrument, because he had suggested the object of the instrument wanted. The instrument spoken of above, that I made for Sir Astley Cooper from his drawings and instructions, was his—not mine; the one that I afterwards made according to my own plan is mine—the idea of it was mine—the principle of it was carried into effect by me; and Sir A. Cooper always allowed me the credit of it. Mr. Guthrie's suggestion was only a modification, as I said before, of my instrument; the merit of his suggestion I neither dispute nor claim; but the instrument with *three* blades is still my invention, as it was before with *two*.

I should not need to encroach upon your space, or to intrude myself upon the attention of your readers on this occasion, were not the degree of merit that fairly belongs to me, too frequently claimed by others, and not only my share of praise, but of “solid pudding,” denied me. The only reward a mechanic can reap from the success of his ingenuity, is the preference given to him in his business, and, at least, the profits arising from making those instruments of his own invention; but the reverse is too frequently the case; it has often happened to me, that my improved instruments have been ordered from other makers, who have never invented any new instruments, but profited by copying those of others. In proof of this, I may be allowed to mention a fact, which shows the extent of the injury that has been done by such misrepresentations as this of Mr. Guthrie, for Sir James M'Gregor wrote to the secretary-at-war, stating, upon whose authority I do not know, that the inventions and improvements to which I laid claim, and had published in my book, did not belong to me, and to that I owe the loss of my business for supplying the army with instruments. Mr. Guthrie being well aware of this circumstance, I am therefore the more sorry and surprised to find him trying to injure what I most value, character and reputation.

I am, Gentlemen,

Your obedient servant,

62, Strand,
26th March, 1834.

JOHN WEISS.

MR. GREEN'S SUGGESTIONS FOR NEW
MODELLING THE MEDICAL PRO-
FESSION.

*To the Editors of the London Medical and
Surgical Journal.*

GENTLEMEN,—Whatever comes before the profession with the sanction of an authoritative name, deserves consideration even beyond its real and intrinsic merits. I view in this light Mr. Green's “Suggestions respecting the Intended Plan of Medical Reform, &c.,” as announced in your last Journal. All my knowledge of it arises from that source, and no doubt you have correctly stated its leading features. The writer evinces a laudable desire to secure to medical practitioners the high advantages of a liberal education; but there is no originality in this, for medical men of all ranks have partaken largely of the prevailing thirst after knowledge in all its necessary and useful departments. But there is also an aristocracy of feeling indicated by Mr. Green, that reminds us of an often quoted apothegm, which fell from the lips of our present distinguished Premier. He appears to say, “our order” must be maintained, and kept at a distance from the commonalty of the profession. The general practitioner is to be an “Inceptor Graduate of Physiology,” with three years' professional education; and should he resolve, as most would resolve, to have five or six years of preliminary qualification, he still appears before the public under a designation which is associated with only half the professional education of the “Doctor in Medicine” or the “Master in Surgery.” The men who have to qualify for the most comprehensive duties, to meet exigencies in medicine, in surgery, and in midwifery, and who, in country practice, cannot obtain assistance in every emergency, are to be allowed to practice with qualifications by no means equal to what are now required of them, whilst the higher order of practitioners are required to go through a process of study much superior to what is now demanded.

I am sure that neither the community nor the general practitioners will feel under any obligation to Mr. Green for his proposition. The former, with rapidly advancing intelligence, will not thank him for his effort to provide a class of medical men, interwoven

with the best interests of society, who are undeserving of their highest confidence; and the latter, with a growing sense of high responsibility, and with a consciousness of having received a measure of respect and confidence somewhat commensurate with their heightened qualifications, will not be satisfied to fall back thirty years as to the relation they sustain to their more honoured brethren, or to abandon a post in which they possess the power of applying knowledge with some efficiency, to one of the best of purposes,—the alleviation of human misery. Will Mr. Green tell us that his considerations have been directed by solicitude to provide a class of men whose education shall not be too expensive? The motive may be laudable, but it is short-sighted. It will be a pitiful economy for a man to prepare for a station in which he will neither ensure respect nor trust, and the boon offered by these concessions, of being authorised to charge attendance, is a requital of little value when that attendance does not ensure the highest reward,—*esteem and confidence*. If the attainment of the higher qualifications is inaccessible to the general body of medical men, it will be far better to lessen the expenses than to lower the competency.

My brethren in general practice, I trust, will ever aim at occupying a position of real merit and utility; and this will not be incompatible with the maintenance of courteousness towards other departments of medical and surgical practice, and of rectitude towards the public. Whether the legislature give the right or not, I have the proof that general practitioners may now, satisfactorily to all parties, abandon the degrading habit of paying themselves by medicine; and this does not interfere with the existence of the most friendly relations to those enlightened men who have chalked out for themselves a narrower circle of practice either as physicians or as surgeons.

I am, Gentlemen,

Your obedient servant,

39, Trinity-square,
April 1st, 1834.

W. COOKE.

PERVIOUSNESS OF THE BODY TO AIR.
Dr. GRAVES cites several authorities—Frank, Dalton, Mitchell—that the whole substance of the body is pervious to air, and that this

fluid may cause emphysema and tympanitis without the secretion of gases and lesion of tissues. It leads to the probability of the existence of gaseous matters of very various kinds in almost every part of the animal frame, resident there molecularly, and not *en masse*, but susceptible of being collected into the great cavities, or the cells of the tissue or blood vessels, by mechanical or electrical influence, or the attractive interstitial agency of other masses of air.”—*Dublin Journ. of Med. Science*.

MEETING OF THE MEDICAL PROFESSION.

A MEETING of the medical practitioners of the city and county of Cork, was held on Tuesday, the 18th ult., Dr. D. B. BULLEN in the chair—for the purpose of taking into consideration a communication about to be made by the Permanent Medical Committee to the Board of Superintendence, for the better regulation of the duties of the medical officers of Dispensaries.

This communication was approved of by the meeting, and ordered to be transmitted to the Board on the following day, with some trifling alterations.

The recommendation of the Committee, if attended to by the Board, will, it is hoped, have the effect of correcting many of the abuses which at present exist in Dispensaries, as far as practicable under a vitiated system of local government, and will serve to protect the medical officers of these establishments in the conscientious discharge of their arduous duties.

The attention of the meeting was also directed to the important investigation into all branches of the medical profession in this empire, which is at present conducting by a “Committee of the House of Commons.” The meeting considered it of the highest importance that proper and useful information should be afforded to the Parliamentary Committee, with respect to the state of the profession in this part of the country, and the many abuses which were allowed to exist in it at present.

This was considered the more necessary, as there is an absolute certainty of the report of the Committee (of which Mr. Warburton is Chairman) being adopted by Parliament as

the basis of some new legislative enactment, to render the profession as useful to the community as possible, and also to increase its respectability.

The meeting accordingly deputed Dr. John L. McCarthy, one of the members of the Permanent Medical Committee of this county, to communicate personally with Mr. Warburton, and to tender evidence on the state of the profession in this county to the parliamentary Committee.

Dr. Bennett, Secretary to the Permanent Medical Committee, was requested to communicate immediately to Mr. Warburton the result of the above meeting, some correspondence having already passed between them on this subject prior to the meeting being held.

French Hospital Reports.

HÔTEL DIEU.

Marked Cerebral Symptoms—No Lesion found in the Brain.

On the 10th of January a youth, *ætat.* 19, was admitted for illness of four days' duration, during three of which he had been delirious; the body was in continual agitation, and his intellectual faculties seemed entirely gone; the face was pale; the pulse small and depressed; tongue dry; small hacking cough; sonorous râle over the sternum; expectoration and difficulty of breathing, from collections of mucus in the air passages. As he had been bled on the evening before, eight leeches were placed behind his ears, cold applications were applied to his head, which was shaved, and an enema with senna was given to him. The question was, whether the symptoms were primitive in the brain, and consequent upon inflammation of its membranes, or whether they were consecutive to the asphyxia, which appeared to threaten the patient, from the collection of mucus in the bronchial tubes: the diagnosis of M. Piorry was meningitis. The cerebral membranes and substance were examined after death, which occurred rapidly, but were perfectly healthy. There was a small quantity of fluid in the spinal canal, but the medulla spinalis was normal; viscera of the abdomen sound; both lungs were in a state of inflammation, and contained small tubercles collected into masses; in the right lung, at the lower

part, there was cavity sufficiently large to contain a walnut.

Epilepsy—Tumours in the Dura Mater—Ramollissement of the Corpora Striata and Thalami Optici.

Marie Chassin, 56 years of age, was seized with symptoms of violent epilepsy, after undergoing various distresses of mind. Delirium supervened on this attack, and lasted many days. On the 7th of January she presented the following symptoms:—contractions and rigidity of the limbs; epileptic tremulousness; some of the movements of the body automatic, others voluntary; she could hear and see, but was unable to answer questions; mental powers affected. Bleeding, cold compresses to the head, and hot cataplasms to the extremities, were prescribed. On the 8th she answered yes to every question: in other respects much the same. Recourse was had to purgative enemata, blisters to the head, &c., but the disease pursued its course, and terminated, on the 13th of January, in death. The diagnosis was epilepsy, inflammation of the left side of the brain, affection of the thalami optici, of the corpora striata, and of the membranes of the brain.

Autopsy.—Chest—Bloody froth in the bronchi; lungs engorged with blood at their inferior lobes; large ecchymosis between the abdominal muscles; nothing remarkable in the digestive canal. *Head*.—Hard fibrous tumours, the size of hemp-seeds, in the dura mater, penetrating into the brain; arachnoid and pia mater injected; the interior of the thalamus opticus and of the left corpus striatus in a state of ramollissement; the brain in the neighbourhood of these bodies also partook of this softening and was of a gray colour, furrowed with red lines.

HÔPITAL DES ENFANS MALADES.

General Œdema—Autopsy.

—DUVAL, *æt.* 8, was admitted with general œdema, which commenced some time previous in the legs, thighs, and scrotum, then made its appearance in the abdomen, and finally, after affecting the superior extremities, attacked the face and eyelids. It did not appear from the history which could be obtained from his mother, that he had suffered, previous to the development of the œdema, from either fever

or palpitation. The pulse was 100; small, but regular; respiration easy; and the digestive organs apparently in good order. By the aid of purgatives and diuretics much relief was obtained, but at the end of some days he was attacked with measles, accompanied by acute bronchitis. He, however, became better, and at his own request was removed from the hospital; on the 23rd of the same month (September) he was again admitted as a patient, with all his symptoms greatly aggravated. The urine was scanty and albuminous; there was pneumonia of the right lung, and great emaciation; the anasarca state still persisting. In spite of treatment, he was attacked with convulsions, became comatose, and died on the 7th of October.

Autopsy.—*Head*—Venous congestion of the membranes; serum beneath the arachnoid, both above and at the base of the brain; cerebral substance itself pale, but of the natural consistence. *Chest*—Three ounces of fluid in each pleura; the superior lobe on the right side hepatized, and containing in the interior a great number of gray semi-transparent granulations; the inferior right lobe partially hepatized, and gorged with blood. In the inferior portion of the right lung, there is a tubercular mass as large as a walnut. Fluid to a small extent in the pericardium. *Abdomen*—Considerable quantity of fluid in the peritoneum and cellular membrane within the pelvis; liver, stomach, and spleen presented nothing remarkable; the kidneys of the usual size, of a yellowish brown colour, soft and friable, and filled with a number of small white points the size of pins' heads. This appearance pervades the whole structure of these organs.

HÔPITAL DE LA PITIE.

Pneumonia--General Bleeding--Large Doses of Antimony Tartarizati—Cure.

A sadler, æt. 58, who had suffered for some time from slight catarrhal attacks, but not of sufficient importance to oblige him to suspend his occupation, was seized in the commencement of December, 1833, with acute bronchitis, which, after lasting six weeks, appeared to have entirely ceased. For nine days he was perfectly free from all symptoms, but at the end of this time, without any evident

cause, he was suddenly seized with rigor, followed by heat and fever; his cough manifested itself again, and was much more vehement and distressing than on the first attack. At this time he was at home, and, although compelled to keep his bed, did not take any other medicine than powdered rhubarb.

On the 30th of January, 1834, the day of his admission into the hospital, the respiration and pulse was accelerated; in the left subclavian region, the sound on auscultation was obscure, but was of the bronchial character; under the scapula of the same side there was evidently the râle crepitant, and a slight echoing of the voice might be heard in this situation. The cough was very troublesome, and was followed by expectoration, the nature of which could not be known, as it had not been preserved. The sensorium was slightly affected; his face was of a pale yellow colour; and for some days his bowels had been constipated. Emollient enemata and bleeding were prescribed, together with a tisane of mallows.

31st. The blood drawn from his arm was cupped and buffed; his pulse has risen a little, and is now 84; the bronchial respiration and the râle crepitant are still audible; the expectoration is viscid and semi-transparent; the bowels have been freely opened; six grains of tartarised antimony, in six ounces of water, were prescribed: a portion to be taken every two or three hours.

Although there is no pain in the side there could be no doubt, according to M. Louis, from the other symptoms, that pneumonia at the upper part of both lobes existed. The exhibition of the tartarised antimony was followed by eight or ten evacuations, and, during the first day, with vomiting; on the following day the dose was increased, the vomiting ceased, and the number of evacuations was reduced to four. M. Louis observed, that the best way of overcoming the diarrhoea and vomiting, caused by the tartarised antimony, was to increase the dose.

At the end of the second day, under the continued employment of this medicine, the symptoms were greatly diminished, the sound under the clavicle was less dull, and the crepitating râle less distinct; the pulse had fallen to 76, and the expectoration was less viscid; in a few days he left the hospital well.

British Hospital Reports.

ST. GEORGE'S HOSPITAL.

Fracture of the Lower Jaw.

WILLIAM STUMMETT, æt. 22, a healthy-looking young countryman, was brought to the hospital, Dec. 13th, by a practitioner from the country, for Mr. Brodie's advice, under the following circumstances. About a month ago he fell from a cart, which did not stun him, but gave him several severe cuts about the head and face, which are now healed. He received from the fall a double fracture of the lower jaw, and there is now considerable swelling of the integumental surface in the neighbourhood, with great displacement of the fractured ends of the bone; the fracture is oblique on either side of the jaw, and is situated partly between the *deas sapientia* and first molar tooth. Considerable force is required to approximate the fractured ends of the bone together. Mr. Brodie made several efforts without success, but told the gentlemen present that he would give the case his best attention, and hoped the result would be favourable.

16th. Mr. Brodie ordered three teeth to be extracted from the upper jaw; the fracture was then reduced after much difficulty and repeated efforts, and a bandage was applied, going over the head and under and around the jaw.

23rd. The fractured ends of the bone have slipped from their position, and there is consequently considerable displacement. He complains of a great soreness of the throat, with much fever. Pulse 121; tongue white; bowels not open; face greatly flushed; skin hot and dry.

R. Hydrarg. submur. gr. iv. h. n. h. s. s.

Haut. sennæ cras primo mane sumend.

Haut. salivæ 3 iss. quartis horis sumend.

25th. Fever abated; tongue clean; bowels open; skin cool.

Jan. 1st. The fractured ends of the bones having been replaced, they are at present in very good apposition. The swelling of the face and soreness of the throat have abated, and the general health is good.

19th. The fracture has partially united, and he was therefore made an out-patient.

MIDDLESEX HOSPITAL.

Syphilitic Iritis in conjunction with Lepra Alphoides.

Fred. Churchill, æt. 24, admitted under Mr. Mayo, Jan. 27, 1834, for an affection of the right eye.

The conjunctiva was inflamed, and presented several congeries of distended vessels; the iris was also changed in colour, being of a cloudy greenish hue, while the left was of a light blue cast. He complained of dimness of sight, but of little pain.

He was also affected with a dry, scaly erup-

tion, the patches of which were thin, white, and circular, and situated upon a dry, red, slightly elevated base, the cuticle over which was exceedingly thin and smooth.

The eruption was situated on the head, face, arms, back, chest, thighs, and prepuce; it was, however, thickest on the back part of the arms, especially near the elbows, on the back, and on the prepuce, which last was covered by it; the face, chest, and thighs had only a few, and these were very small. As the history of the case, he states that six months ago he had an attack of gonorrhœa, for which he took cubets and purgative medicines. Three months subsequently he had a small sore on the end of the glans penis, and swellings in both groins, for which he took a little mercury, and applied some leeches. The sore soon healed, but the swellings remained for six weeks, and then subsided.

Three weeks previously, however, to the swellings in the groin subsiding, an eruption of small red pimples made its appearance on the arms; these increasing in size, were surmounted by whitish mealy scales, which soon fell off, and were followed by others of a larger size, circular form, and of a more opaque white colour. This process of falling off and reproduction was frequently repeated, as the bases extended themselves; the scales in several places attained the size of a sixpence, the others varying in size from that down to a mere pimple. The bases were, as already stated, slightly raised, red, and dry, there never having been any discharge from them. The gonorrhœa had only ceased about ten days before his admission.

Hirudines xij. Temp. diet.

Calom. gr. ij., patr. opii. gr. ss. 4tis horis sumendus.

24th. Eye much relieved by the application of the leeches; iris more clouded, and the pupil more contracted and irregular.

Pil. hydrarg. gr. x.

Pulv. opii, gr. ʒ. Misc. o. nocte.

Pil. hydrarg. gr. v. o. mane.

and as the bowels had not been relieved for several days,

Ol. ricini 3vj. statim.

Feb. 9th. In about five days after taking the last prescribed medicine the mouth became a little tender, from which time the eruption has been evidently yielding, the scales falling off, and either not being again replaced, or, if so, being exceedingly thin, and not so firmly attached.

The iris is not quite so discoloured, but is still cloudy; the dimness of sight is not as yet altered, and the conjunctiva is becoming more inflamed.

Hirudines viij. Temp. diet.

Rep. pil.

10th. The eye is a little but not much relieved, the vessels of the conjunctiva being still distended.

Hirudines et temp. diet.
Rep. pil.

16th. Inflammation of the eye abated, and the iris is regaining its natural colour; the sight, however, is not at all improved. The scales have continued falling off, there being now but few remaining. The mouth is not more affected than when previously mentioned, there being only a very slight distaste in it, and a trifling degree of tenderness.

Rep. pil. hydrarg. c. opii, o. nocte.
Pil hydrarg. gr. x. o. mane.

21st. The opacity and discoloration of the iris are now removed, it having regained its natural colour; the margin of the pupil is still however slightly irregular. The sight is much clearer than it was, but he still complains of things appearing as in a mist.

WESTMINSTER HOSPITAL.
Encysted Tumour of the Scalp.

A few days ago a middle aged woman was brought into the operating theatre, having a large oval tumour on the back of her head. She stated, that some years ago she had received a blow on the part from a pole falling on her head: soon after this swelling made its appearance, and gradually increased in dimensions. Sir Anthony Carlisle having made an incision in the tumour, a considerable quantity of a yellowish fluid escaped; he then lost no time in carefully removing the cyst from its surrounding attachments. Adhesive plaster was then applied to the incision, and the patient walked home.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXXIV., DELIVERED APRIL 9, 1833.

GENTLEMEN,—Let me this evening request your attention to *Diseases of the Eyelids*, and I may begin with observing, that *inflammation of the eyelids* is not so disposed to involve the eyeball, as external inflammation of the latter is to extend itself to the former. However, if the inflammation of the eye be restricted to its internal textures, then the eyelids are not affected. When abscesses form in the cellular tissue of the eyelids, an early opening should be made in them, as the most likely means of preventing the extension of the disease, and subsequent eversion of the part. Passing over wounds, phlegmonous and erysipelatous inflammation of the eyelids, the treatment of which is regulated by general principles, I request your attention first to

Catarrhal Inflammation of the Eyelids, which affects their mucous membrane and the glands of Meibomius, beginning near the margins of the eyelids, which become sore, and are affected with heat and dryness. The lining of the lids assumes a red, thickened, and villous appearance, so that, if everted, it will sometimes look like a piece of scarlet velvet. When the lids are moved, the pain is severe, because then the inflamed surface rubs against the globe of the eye; and hence you will generally remark that, in every severe case, the patient keeps the eye more or less shut, and the eyelids motionless. In the beginning of the attack, the natural mucous secretion is suppressed, and hence a sensation of dryness and stiffness; but, after a little while, this feeling subsides, because now the secretion of mucus recommences, and is even more

abundant than natural, though altered in quality, and somewhat like pus. The secretion from the Meibomian glands is also changed, so that it has a share in making the eyelids stick together, which happens in the night in such a degree, that the patient cannot open the eye in the morning.

Catarrhal inflammation of the eyelids is mostly produced by atmospheric causes, and such as usually bring on inflammation of other mucous membranes. But inflammation of the lining of these parts is sometimes owing to its being habitually exposed to the irritation of smoke, or of an atmosphere impregnated with gas or vapour of a stimulating kind, minute particles of lime, &c. The influence of any of these causes will be rendered more powerful, if the patient be uncleanly, or intemperate.

Gentlemen, the *treatment* is of the following kind. In the early stage, during which the inflammation is always more or less acute, antiphlogistic remedies are proper: apply leeches, tepid lotions, and the unguentum cetacei, to the edges of the eyelids, in order to keep them from becoming adherent in the night-time. Let the patient's bowels be kept well open; at first, indeed, it is better to give him some brisk purgative medicine. These means, if the case be one of sufficient severity, are to be followed up by a blister on the nape of the neck. When the acute form of the complaint has been subdued, you must employ astringent lotions, and stimulating applications, especially the vinum opii, and the ung. hydrarg. nitratis, which latter is to be melted, and put on the edges of the eyelids with a camel hair pencil. At first, it ought to be weakened by being mixed with an equal quantity of the ung. cetacei.

Ophthalmia Tarsi, or *Psorophthalmia*, is merely a chronic inflammation of the lining of the eyelids, or rather, I should say, of their margins, occasioning their adhesion together in the night, a degree of soreness and itching in the parts, and a falling off of the eyelashes. The Meibomian glands are considerably implicated. When the lining of the eyelids has been frequently in the state of chronic inflammation, especially in old subjects, not only are the eyelashes lost, but the edges of the

lids, instead of being angular, become rounded, and present an habitually raw and red appearance, which is technically named *lippitudo*, or *blearedness*.

When ophthalmia tarsi has continued for a long while, or been neglected, the orifices of the ducts of the Meibomian glands, placed along the inner margin of one or both eyelids, may be partially or totally obliterated; and it is chiefly in such examples that you will observe that the eyelashes are lost, and the edge of the lids rounded off. Sometimes, indeed, an eversion of the lower eyelid takes place, from a contraction of the frequently excoriated parts of the adjoining skin of the cheek, or you may have an inversion of the part, from the effect of previous ulcerations on the inside of it.

When a person is troubled with ophthalmia tarsi, or psorophthalmia, he should never attempt to open his eyes in the morning, till the glutinous matter, which makes the eyelids and eyelashes adhere together, has been properly softened and dissolved, so that it may be done without pain. For this purpose, the margins of the eyelids and the eyelashes should be anointed with a small quantity of spermaceti cerate. Then a piece of soft sponge, wrung out of hot water, is to be held over the eyelids for a few minutes, after which the eye will admit of being opened without pain. All the gummy matter should be removed, because, so long as it remains, no eye-water nor salve can be brought in contact with the principal seats of the complaint.

The first indication, or that of diminishing inflammation, may be further promoted by fomenting the eyelids with a decoction of camomile flowers, applying leeches to the eyelids, and giving aperient medicines.

In very bad cases, I recommend you to cover the eyelids at night with a bread and water poultice, included in a bag of fine muslin, the margins of the eyelids being first smeared with a little of the spermaceti ointment.

The second indication, or that of healing the ulcerated and excoriated parts of the lid, is fulfilled by applying to them the unguentum hydrargyri nitratis, more or less weakened at first with a proportion of lard. I like this ointment as well as any; but certain practitioners are in the custom of using others; as, for instance, salves, containing the red or white precipitate of mercury, in the proportion of 10 or 12 grs. of the former, or 30 grs. of the latter, to an ounce of lard.

When you notice small ulcerations along the margins of the eyelids, I recommend you to touch them with the nitrate of silver, or a strong solution of it; and, in bad cases, it is best, before using the caustic, to extract the eyelashes, for if their bulbs are suffered to be destroyed by the ulceration, they will not be reproduced.

The third indication, or that of improving the general health, requires the employment

of tonic and alterative medicines, sea bathing, pure air, and regular exercise.

The *hordeolum*, or *stye*, is generally compared to a little boil, of about the size of a barleycorn, projecting from the eyelid. It is of a deep red colour, attended at first with itching, and afterwards considerable tenderness, and even more pain than might be expected from so trivial a swelling. Sometimes the irritation is such, that the conjunctiva is partially inflamed, and the motion of the eyelid productive of great annoyance. It is the nature of a stye to suppurate very slowly; but at length it does suppurate, points, and bursts; and after discharging a minute quantity of curdy matter and disorganised cellular membrane, it usually subsides and disappears. But if any of the sloughy matter remain within it, the disease is apt to return, or to degenerate into a hard, white, chronic tumour, that is very slow in undergoing any change, and is technically named *grando*, from having been compared to a hailstone. I have attended young persons, who have been annoyed for several weeks by a succession of styes, one forming as soon as another had been cured.

The treatment of a stye may be of the following kind. In the beginning, cold applications, as the lotio plumbi acetatis, or a cold bread poultice, made with the same or iced-water, are proper; but you will rarely succeed in preventing the disease from coming forward. However, you may first try what cold applications and aperient medicines will do; and when suppuration is obviously taking place, exchange them for warm poultices and fomentations. As soon as you see a white point on the apex of the little tumour, provided the tumour is slow in bursting of itself, I advise you to make a small puncture in it; but avoid doing this unnecessarily or prematurely, as you would thus only increase the inflammation, without obtaining any discharge of what is contained in the stye. The pus and sloughy cellular substance are then to be pressed out, and the poultice put on again. When the sloughy cellular membrane is slow in coming out, the cavity may be touched with lunar caustic, or with the end of a probe dipped in sulphuric acid.

I think the best way of treating the tumour termed *grando*, or *chalazion*, is to open it, press out its contents, and touch the interior of the cyst with a piece of lunar caustic scraped to a point.

The next subject, gentlemen, is *encysted tumours of the eyelids*, which are not unfrequent cases, their seat being generally in the cellular substance, connecting the integuments of the lid with the orbicular muscle; but they may be more deeply placed, so as to be covered not only by the orbicularis but by the levator muscle. The more fluid kinds sometimes grow to the size of a pigeon's egg; but the steatomatous ones rarely become larger than a filbert. These tumours

often contain, besides the ordinary matter of encysted swellings, small short hairs, entirely destitute of bulbs and tubes.

The encysted swellings, not closely connected with the tarsal cartilage, are to be treated precisely on the same principles which apply to ordinary swellings of a similar character in other situations; but if they should be intimately connected with that cartilage, a formal dissection of them out would be difficult without cutting a portion of the cartilage away. Now this kind of operation is found to be needless. The best plan is to evert the eyelid, and, at the point where it appears to be thin and most closely connected with the base of the swelling, to make a free puncture through the cartilage, by which the contents of the swelling, if fluid, will be discharged; but if found not to be fluid, a second cut may be made across the first, and the four angular flaps snipped off with scissors.

Gentlemen, no doubt all of you have had opportunities of seeing what is termed *ectropium*, or *eversion of the eyelids*, a case productive of vast annoyance and considerable disfigurement. The lower eyelid is most frequently affected, its edge falling downwards and forwards away from the eyeball, which is no longer duly covered and protected. This exposure of the lower portion of the eye, and of the conjunctiva of the eyelid, produces in these parts a degree of inflammation, attended with constant pain and redness, and thickening of the membrane, which is at length converted into a hard callous substance, lying just under the eyeball. As the flow of tears towards the inner angle, and through the puncta lachrymalia, is also obstructed, they fall over the cheek, which is apt to become excoriated.

Ectropium may arise from various causes, which considerably influence the treatment; for it may be either a permanent or only a temporary deformity, which will subside of itself on the abatement of the inflammation that has given rise to it. Thus you will meet with *ectropium from acute inflammation of the conjunctiva*. When it affects the upper lid, it is in some degree accidental. A child, for example, is labouring under acute purulent ophthalmia, and the surgeon, in order to examine the eye, or remove the copious discharge, everts the upper eyelid, the child begins to cry violently, and all attempts to reduce the lid to its natural position are found to be ineffectual. It soon becomes greatly distended with blood; and even, if it admit of being replaced, it is generally everted again as soon as the child begins to cry. When this variety of ectropium affects the lower eyelid, it is not produced in this accidental way, but altogether by the swelling and protrusion of the inflamed conjunctiva.

Here you must foresee, without my mentioning it, that the *treatment of ectropium from acute inflammation of the conjunctiva*

requires, 1st, scarification of the everted conjunctiva; 2nd, after the swelling of the eyelids has been lessened by the discharge of blood, the part may generally be reduced; 3rd, if the inflammation be not very acute, the lid is to be kept from quitting its natural position by means of a compress and roller. In the contrary case, every thing must be avoided likely to make the child cry; and the attendants are to be instructed how to replace the eyelid, if it should happen to become everted again. A collyrium containing alum, the nitrate of silver, or sulphate of copper must be applied frequently, for the purpose of checking the purulent discharge.

When scarifications fail to remove or prevent the eversion, you may cut away a portion of the swollen conjunctiva. The bleeding which follows will prove of great service. Afterwards strips of plaster, passed from the upper to the lower lid, and a compress and bandage will prevent the return of the displacement.

Ectropium of the lower eyelid from relaxation is most frequent in elderly persons, as a consequence of *chronic inflammation of the conjunctiva* and Meibomian glands. From constant exposure, the inside of the everted lid becomes red, firm, and almost insensible, and the lower punctum lachrymale displaced forwards. These various circumstances are necessarily productive of a weeping of the eye, a *stillicidium lachrymarum*, and of various degrees of inflammation of the eyeball itself.

I may next inform you, gentlemen, that the *treatment of ectropium of the lower eyelid from relaxation* consists, first, in removing the inflamed state of the eyelids and conjunctiva, and then in applying escharotics to the exposed conjunctiva, for the purpose of obviating the tendency to a return of the displacement. I recommend you to try scarifications of the inflamed conjunctiva, and subsequently to apply the sulphate of copper, or nitrate of silver, and a compress and roller. In inveterate cases, a portion of the thickened and relaxed conjunctiva is to be removed.

Gentlemen, there is a species of *ectropium of the lower eyelid, consequent to excoriation of it and the cheek, resulting from long-continued ophthalmia tarsi*, and it is alleged to be one of the most common forms of the disease. In this case, you will notice that the edges of the lid are rounded off, the orifices of the Meibomian glands partially or completely obliterated, the eyelashes destroyed, and a considerable portion of inflamed conjunctiva exposed to view. The ophthalmia tarsi is to be removed by the means explained in the last lecture. The skin of the everted lid is to be smeared with zinc ointment, and the exposed conjunctiva scarified and touched with nitrate of silver. Should these means not prove effectual, a portion of the conjunctiva must be removed. In bad cases, resisting this treatment, the practice of cutting out a portion

of the cartilage of the shape of the letter V is sometimes adopted.

Next, gentlemen, I may briefly advert to the *ectropium of the lower eyelid, from disunion of it from the upper one at the temporal angle*. This is seldom seen, except in old persons who have been long afflicted with inflammation of the margins of the eyelids, and have had a succession of ulcers near the outer commissure. The treatment requires an operation similar in principle to that performed for the cure of harelip, namely,—the edges of the disunited commissure are to be cut off, and the parts then united by means of a suture. The diseased state of the eyelids, however, should be first cured.

Of Ectropium.—Most of the examples, which I have met with, have arisen from the *contraction of a cicatrix*. In fact, the deformity is not an unfrequent consequence of a wound, an abscess, an ulcer, or a burn. In slight cases the simple operation of removing a fold of the conjunctiva may be sufficient; but some examples are met with in which the degree of eversion is very great, the length of the eye-lid in the transverse direction much increased, and its outer surface fixed by adhesions. Here the cicatrix must first be divided, in order to loosen the lid from its unnatural position, and then a portion of the conjunctiva is to be removed; but, for the purpose of counteracting the morbid elongation of the lid from one canthus to the other, it is sometimes necessary to remove a portion of the whole thickness of the tarsal cartilage, shaped like the letter V, and then bring the edges of the wound together with a suture.

Then, gentlemen, amongst the numerous diseases of these parts I have to explain one to you, which is exactly the reverse of the preceding: I allude to what is named *entropium* or *inversion* of the eyelids, which is mostly seen in old subjects, in whom the skin of these parts is loose and redundant, and thrown into folds. When the upper eyelid is inverted in the slightest degree, a considerable irritation of the eye is produced; but when a large portion of it is so displaced, the case becomes truly afflicting. The friction of the eyelashes against the eye is incessant, attended with immense suffering, the eye itself inflames, the cornea ulcerates, or becomes opaque, and the eye-sight is ultimately destroyed.

When proper treatment is adopted early, the entropium may generally be cured by cutting away a fold of the integuments, near the edge of the tarsus. You first take up a portion of them with the entropium forceps, and observe whether what you hold is sufficient to bring the eyelid into its right position; if so, you cut it off with a small pair of curved scissors, and unite the edges of the wound with one or two sutures, which you may withdraw the next day, as the wound will then have united.

Another method of cure is that of producing

a contraction of the skin of the eye-lid, by cautiously applying across its central part a little sulphuric acid, by means of a thin bit of wood dipped in it, and rubbed upon an oval space, a little longer than the extent of the inversion, and from three to six lines in breadth. Three or four applications will generally suffice.

But, gentlemen, I must tell you, that more difficult cases are met with, arising from an alteration in the shape of the cartilage of the eyelid. For these the common plans will not answer, and you must try others. One consists in making two perpendicular incisions in the broad margin of the tarsus, at the sides of the inverted part, and then making a transverse cut through the lining of the eye-lid, from the extremity of one of the first wounds to that of the other. The inverted portion of cartilage, thus comprised within the incisions, is then to be put into its right position, and retained in it with sticking plaster.

When the vicious shape of the tarsal cartilage makes the adaptation of it to the eye impracticable, its total excision has been occasionally performed.

Sometimes it seems as if the entropium depended upon the cartilage being too short; for if you make a cut through the outer commissure, it no longer presses against the eye. Another kind of operation is that adopted by Jaeger, of Vienna, and which consists in paring away the edge of the inverted tarsus.

In the next place, gentlemen, I may speak of *trichiasis*, which properly signifies the growth of the eyelashes in such a direction, that they rub against and irritate the eyeball.

You seldom find all the eyelashes turned toward the eyeball, except when trichiasis is really accompanied by an inversion of the eyelid. The inconveniencies of the complaint are severe, for the friction of the eyelashes against the eye brings on inflammation of that organ, and, in time and under neglect, opacity of the cornea and blindness. The wrong direction of one or more of the eyelashes is often overlooked, and the effect, the inflammation, only attended to; now here, as in every other part of surgery, I advise you to search the cause of the disease, and not to disregard it in the treatment. Its removal will alone frequently suffice.

One plan of treatment consists in removing, one after the other, all the inverted cilia by means of forceps. Each eyelash is to be laid hold of, as close as possible to the skin, and pulled out quickly in a straight direction; but, in general, the result is only a temporary relief, as the hairs grow again. Hence, I believe, the best way is to pare off as much of the ciliary margin of the eyelid as will include the bulbs of the inverted eyelashes.

When trichiasis is merely an effect of entropium, the eyelashes need not be extracted, as the cure is brought about by the measures applicable to the entropium.

Distichiasis, gentlemen, strictly means a

Double row of eyelashes; but, in fact, the supernumerary cilia are never arranged in this regular order, nor do they usually extend the whole length of the eyelid, but are scattered at different points, between the natural place of the eyelashes and the orifices of the Meibomian glands.

Cases also sometimes present themselves, in which strong hairs grow from the inner concave surface of the eyelids.

The only effectual mode of treatment is to extract the hairs and their bulbs.

Next I may bring under your notice *ptosis*, a term signifying an inability to raise the upper eyelid, which hangs loose and pendulous over the globe of the eye. In some examples this depends upon excessive distention and inflammation, but what is more commonly understood by *ptosis* is that form of it, which is accompanied by paralysis of the levator palpebræ superioris.

If the eyelid be lifted from the eye it gradually sinks down again by its own gravity, being often slightly oedematous, the eye looking dull, the iris being less irritable than natural, the pupil dilated, and the eye frequently amaurotic.

Ptosis is generally symptomatic of disease of the brain, and the treatment must be regulated accordingly. With due attention to the cause, however, there is no objection to rubbing the eyelid with camphorated mercurial ointment, or with liniments containing ammonia or camphor, or to blistering the neighbouring part of the forehead.

Paralysis of the Orbicularis Muscle sometimes follows operations performed near the lower extremity of the parotid gland, and producing injury of the branches of the portio dura of the seventh pair of nerves. As far as the eye is concerned, the consequences are not usually serious, and the inconvenience is that of not being able completely to shut the eye; a state to which the term *logophthalmos* is applied, whether arising from palsy of the orbicularis muscle, or a shortening or retraction of the upper eyelid itself. However, *logophthalmos*, when it exists in a considerable degree, may bring on inflammation of the conjunctiva, opacity of the cornea, and even *staphyloma*.

The *Granular Conjunctiva*, gentlemen, is mostly an effect of severe purulent ophthalmia, and consists of a rough, hard, granulated state of the lining of the eyelid, attended with a thin or puriform discharge, a varicose affection of the vessels of the sclerotic conjunctiva, an opaque appearance of the cornea, great tenderness of the eye, and an incessant epiphora, or copious effusion of tears. In recent cases leeches are to be applied near the eye, and the granular surface of the eyelid smeared with the melted ung. hydr. nitratis by means of a camel-hair pencil, or rubbed with the sulphate of copper or nitrate of silver. For this purpose the eyelid should always be completely everted, as there is sometimes a semilunar

fringed excrescence at the angle where the conjunctiva passes from the globe to the eyelid, which might otherwise escape attention. After caustic has been used, the eyelid must be bathed with tepid water before it is returned into its natural position again.

Sometimes when the granular productions are remarkably hard, callous, and pendulous, excision is to be preferred.

Concretion of the Eyelids.—Two varieties are met with: in one, the inside of one or both eyelids is adherent to the eyeball (*symblepharon*); in the other, the edges of the two eyelids are connected together (*anchyloblepharon*). This last case is sometimes, though rarely, a congenital malformation; and when it occurs, it is mostly as the result of violent inflammation or burns. The treatment consists in dividing the adhesions with a knife, guided along a director, so as not to injure the eye itself, and keeping the edges of the wound asunder. If the cornea be known to be opaque, such an operation is useless.

As for adhesions of the eyelids to the eyeball, it is only when they are loose and of limited extent, and not situated over the cornea, that the division of them can be of any service.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XVI.

Diagnosis of the Rupture of Hepatic Abscess—Pulmonary Openings—Case of Double Opening—Puncture of Gall Bladder—Gangrene of Liver—Connexion with Hepatic Apoplexy—Diagnosis of Distended Gall-Bladder—Its Causes—Inflammation of the Parietes over the Liver—Sympathy of the Integuments.

GENTLEMEN,—I broke off at my last lecture while engaged in considering the phenomena of hepatic abscess, and you will recollect I spoke of the various modes in which these abscesses may open internally, and stated that the diagnosis in all cases was founded on the same principle, which is this,—that during the prevalence of symptoms indicating the existence of suppuration of the liver, some new organ becomes *suddenly affected*, the nature of the affection being what would be produced by the sudden rupture of an hepatic abscess and a discharge of pus into some of the neighbouring viscera, and this coinciding with the disappearance, more or less, of the original tumour. Now, when we consider the various internal openings of an hepatic abscess, we find that they admit of being divided into two classes, first, those in which the matter is effused into cavities having a communication with the exterior of the body, as the lung,

digestive tube, and kidney. Here, in addition to the symptoms already alluded to, we have a sudden discharge of pus from the stomach or bowels, from the lungs, or by the urinary passages. But we may also have the matter discharged into shut cavities having no external communication, as where the contents of the abscess open into the peritoneum, pleura, or pericardium. You will readily perceive, that of these two classes of openings, those in which the matter escapes into cavities having no communication with the exterior are the most unfavourable. The confined pus excites violent and generally fatal inflammation, and we have a dangerous empyema, a rapid peritoneal inflammation, or intense pericarditis.

I stated, that of the internal openings of an hepatic abscess, one of the most favourable is that in which the matter is discharged into the right lung, and I described briefly the mechanism of this curious process. We are warranted, I think, in declaring this to be a fortunate termination, because there are many instances on record of persons having recovered under such circumstances. A very near relative of mine presented an example of this. He was attacked with symptoms of acute hepatitis, for which he was attended by some of the most eminent physicians in Dublin. His treatment was bold and vigorous; he had free bleeding, both general and local, mercury, and every other means calculated to remove inflammation, but all proved ineffectual. His pulse became rapid; he began to sweat; the hepatic tumour increased in size, and presented a distinct sense of fluctuation; there could be no doubt of the existence of suppuration in the substance of the liver. One morning he was suddenly seized with a violent fit of coughing, and during the course of the day expectorated more than a large tea-cupful of pus; towards evening this increased, and on examination it was found that the tumour was remarkably diminished. The expectoration continued during the whole night, and in the morning it was observed that there was scarcely any appearance of the hepatic swelling. It was singular, and tends to confirm the idea that the matter had been discharged into the lung, that in the erect position, this gentleman had scarcely any expectoration, but in the horizontal, it was always extremely copious; a circumstance which you can easily understand by considering that in the recumbent posture the purulent matter would find a more easy passage into the lung. In this case, it would appear that the communication between the liver and lung was very free, for I remember that on one occasion by making pressure over the liver, he said I was forcing the matter into his chest, and the pressure was followed by an instantaneous and copious expectoration. This frequently occurred. A medical friend of mine, residing in Dublin, mentioned to me some time since the case of a large robust drayman, addicted to whiskey

drinking, whom he attended for an attack of acute hepatitis. At a time when the liver was very much increased in size, and well-marked symptoms of suppuration present, he observed that sudden expectoration of pus took place, which continued for several days, with manifest subsidence of the hepatic tumour and complete recovery. Three cases of this kind came under my notice in the Meath Hospital. One of the patients had symptoms such as I have before described as exhibiting a striking similarity to yellow fever, from which he recovered, and was discharged, with no other remarkable symptom but quick pulse. Shortly afterwards he returned, complaining of pain in the right hypochondrium, with rapid pulse, profuse night sweats, and a slight cough. At first his appearance struck me as being characteristic of phthisis, and under this impression I repeatedly examined the chest by the stethoscope and percussion, but could not detect any lesion. The man had only a slight cough, and this was totally insufficient to account for his symptoms. The nature of the case was soon manifest: one morning the patient stated that he felt as if something had given way in his chest during the night, and he was from that time expectorating *large quantities* of purulent matter. On examining the lower portion of the left side, I found that it sounded completely dull on percussion, and that the physical signs of an accumulation of fluid in the bronchial tubes were extremely distinct. That this dulness was the result of the effusion in question is proved by the previously healthy state of the lung. The very day before I had carefully examined this part of the chest, and found it quite healthy. There was not the slightest resonance of voice in this portion after the accident, because the tubes were so completely filled; so that in this case the return to health was accompanied by *increase of broncophonia*, a fact that sets the question of the nature of the accident at rest. It may appear strange that in this case the puriform matter entered the left lung instead of the right; but this is sometimes the case, particularly when the abscess forms in the left lobe of the liver.

I shall now draw your attention to the particulars of a case, which I look upon as almost unique, and which derives additional interest from the accuracy of the diagnosis. It is of great importance that you should have clear ideas on the subject of hepatic abscess, for, though the disease is not of common occurrence in this country, still, if called on to pronounce an opinion on a case of this kind, the least difference in the quantity of your information may be of consequence. The patient, who was the subject of this disease, was admitted into the wards of the Meath Hospital in August, 1828. The history of his case was, that he had been labouring, some time previously, under obscure symptoms of an hepatic affection, accompanied by slight fever and jaundice, which had gradually subsided.

Three weeks before admission he stated that he had irregular fits of shivering, followed by sweating, and when he came to the hospital he complained of sickness of stomach, but particularly of cough and difficulty of breathing, which were extremely harassing, and said that he came in chiefly to be cured of his cough. He was considerably emaciated, and looked pale and low, but his stools had a natural appearance. On considering the history of his case and the symptoms then present, it struck me that it was either hepatitis with suppuration, or empyema of the right side with irritation of the liver. At that time I had not made my researches on the diagnosis of empyema, and I must confess that I experienced a great deal of difficulty in determining the nature of the case. I found the right side considerably dilated, with dulness on percussion over its inferior half, but the intercostal spaces were not distended, and preserved their natural appearance. The case went on in this way for some time. Permit me to draw your attention for a moment to this point. Dilatation of the right side may result from the pressure exercised upon it by a solid or by a fluid mass. If the mass be solid it will push the ribs outwards, but the intercostal spaces will still preserve their natural appearance. But if the protrusion of the side be the result of pressure by a fluid mass, the intercostal spaces will be acted on even more than the ribs, and the sulci, which mark their situation, will be effaced. Now, in this case the intercostal spaces were evident, and from this circumstance I determined that it was a liver disease. The patient continued for a fortnight without exhibiting signs of any material change, and then the tumour increased very much in size, but there was no appearance of pointing. At this time the patient was visited and examined by a number of medical men, and all agreed that it was a case of deep-seated suppuration of the liver. Under these circumstances it was thought advisable to make an incision through the integuments down to the peritonæum, as recommended by Dr. Graves, and to keep the wound open by filling it with lint. This operation was performed, and the wound kept open for several days, but no matter came. On the sixth day the patient began to sink, his face became hippocratic, his extremities cold, and every one thought he was dying. During the course of the day it was observed that there was a circumscribed tumour, with a distinct sense of fluctuation, situated close to the wound, and towards the right side of the mesial line. Here is an important stage of the case;—a man presenting evidence of suppuration in the liver has an operation performed on him to favour the exit of pus externally, and some time after this we find a circumscribed fluctuating tumour, nearly in the situation of the wound. We concluded that the hepatic abscess was pointing in that situation, and it was determined to pass a lancet cautiously into the tumour. This was

done, but to our astonishment, instead of pure bile escaped through the incision. It was clear that we had mistaken a distended gall-bladder for an abscess, and this I need not tell you was a serious error. It is singular, however, that the accident was not followed by any bad consequences. About two hours after the operation the patient went to stool, and passed two large evacuations, consisting chiefly of a vast quantity of purulent matter. Next morning he was surprisingly well, and the hepatic tumour had considerably diminished. His countenance recovered its natural expression, his spirits were quite elated, his pulse had become tranquil, and the liver was manifestly returning to its ordinary dimensions. He began to sit up, was put upon generous diet, could walk about the ward, and was talking of leaving the hospital. From the period, however, at which the discharge of pus took place he had an obstinate diarrhoea, and though he took a great deal of nourishment he was still pale and emaciated. Twenty-two days after the subsidence of the tumour, another swelling began to make its appearance in the epigastrium, which increased daily, and it was obvious that another abscess was forming in the left lobe. About a fortnight after this he was suddenly seized with excruciating pain in the epigastrium, followed by symptoms of peritonitis. The tumour in the epigastrium subsided, but the patient sank in a few days of the peritoneal inflammation. Let me recal the circumstances of this case. First, we have obscure signs of the existence of abscess, then the sudden escape of matter from the bowels, accompanied with subsidence of the hepatic tumour; in the next place a persistence of diarrhoea and emaciation, and lastly, we have a new tumour in the epigastric region, disappearing on the supervention of symptoms of acute peritonitis. From a consideration of all these circumstances I stated to the class that I should expect to find evidences of the abscess in the right lobe, which was the first affection, and I ventured to say, that the opening between it and the intestinal tube was still pervious. I was led to form this opinion from observing the persistence of the diarrhoea, to check which all the ordinary remedial means had failed. This was the first part of the diagnosis. In the next place I stated my belief, that the gall-bladder had been punctured, but could not explain why the bile had not escaped into the peritonæum. Thirdly, I said, that an abscess had formed in the left lobe, which had discharged its contents into the peritoneal cavity. All this was stated publicly, and on consideration you will find that there was no great difficulty in making the diagnosis. On dissection, we found a cavity in the right lobe, with a small quantity of matter in it, and having a free communication with the duodenum. The fundus of the gall-bladder was found adhering to the parietal layer of the peritonæum, and the mark of a lancet wound in it was evident.

A recent abscess was discovered in the substance of the left lobe of the liver, from which the matter had escaped into the peritonæum by a passage capable of admitting a small quill. Every part, therefore, of the diagnosis of this case was perfect, and borne out by the necroscopic appearances. You will see the details of this very interesting case in a paper published by Dr. Graves and myself, in the 5th vol. of the Dublin Hospital Reports.

This case is exceedingly interesting, because it illustrates two remarkable terminations of hepatic abscess: in one instance, by opening into a cavity which had an external communication, in the other, into a shut sac. The patient recovered from the first abscess, and would have done so effectually if the fistula had closed (no uncommon event); but he could scarcely have recovered from the second, because where the matter escapes into the peritonæum or pleura, the patient almost invariably dies of acute inflammation of these cavities. This case derives additional interest from the circumstance of the gall-bladder having been opened. I believe this is the only case on record in which an opening made into the gall-bladder has not been followed by fatal consequences. I might detail many other cases of hepatic abscess, but I must at present refer you to the paper already alluded to, in which we have published the results of our experience on the subject.

Some authors have mentioned gangrene, or mortification of the liver, as one of the modes in which acute hepatic inflammation may terminate. It is now, however, agreed, that this is one of the rarest terminations we can meet with; in fact, that there is hardly any organic disease which so seldom occurs. Mr. Annesley states, that in all his dissections (and these were very numerous) he never met with a case of gangrene of the liver. Andral, who has examined some thousands of bodies, has only met with a single case: this, with another which was under the care of Dr. Graves, and appears to have been a genuine example of mortification of the liver, are almost the only cases of which I have any distinct recollection. The case under Dr. Graves was that of a patient in Sir Patrick Dun's Hospital, who laboured under chronic inflammation of the liver, with ascites, jaundice, swelling of the lower extremities, and an incapability of lying on the left side. After this man had been about eleven days in the hospital he began to complain of tenderness and pain of the belly; he was next seized with vomiting, and threw up a large quantity of fetid matter. Soon after this he sank, and on dissection, numerous marks of chronic disease were found in various parts of the substance of the liver; but in the left lobe there was a cavity which was distinctly gangrenous, and had in the centre of it a large mass of slough. I think that there can be no doubt that in this case the disease was actual gangrene of the liver. I think, too, it may be very fairly doubted, whether gangrene of the

liver is the result of inflammation, properly so called, in any case; and I believe it would be a very interesting subject for inquiry, to consider how far this disease may be the result of hepatic apoplexy, or effusion of blood into the substance of the liver. This is an accident to which the liver, as well as every other parenchymatous organ, is subject; and though effusions of blood into its substance are by no means so common as similar occurrences in the brain and lungs, still it does not enjoy any thing like immunity from such lesions. We have good reason to believe, that in many cases, blood effused into the substance of parenchymatous organs may, under certain circumstances, either undergo putrefactive decomposition and form a gangrenous abscess, or that, although no longer circulating in its vessels and effused into the parenchyma of an organ, it may still retain its vitality to a certain extent, and, being modified by the powers of life, may give rise to the formation of various morbid products. In this way it is thought that various tumours—cancerous, steatomatous, melanotic, and encephaloid—may originate. I am inclined to think that this sometimes occurs in the brain and lungs, and it is probable that it may happen in the case of the liver also. Further researches, however, are necessary, with respect to the elucidation of this matter, before our opinions on it can possess a higher character than that of verisimilitude.

While on the subject of hepatic abscess, it will be necessary to allude to one of its occasional complications—distended gall-bladder, because this may be mistaken for the pointing of an abscess, and an operation be performed, and that this has happened more than once is a positive fact. A distended gall-bladder has been mistaken for the tumour formed by the pointing of an hepatic abscess, an opening has been made into it under this supposition, bile has escaped instead of pus, and this getting into the cavity of the peritonæum, has given rise to rapid and fatal peritonitis. A remarkable case of this kind has been detailed with great candour by the late Mr. Todd, in one of the early numbers of the Dublin Hospital Reports. He was called suddenly to visit a girl, whom on his arrival he found to be in a dying state, labouring under great distention of the belly, almost insensible, moaning constantly with her jaw fixed, and presenting a distinct tumour in the hypochondriac region, which from the history of her case, he was led to consider as an hepatic abscess pointing externally. He divided the integuments and muscles down to the peritonæum, and having introduced a trochar, drew off nearly three pints of *bile* with apparent relief. Shortly afterwards, violent peritonitis came on, and the patient sank rapidly. After death the liver was found to be healthy, and the tumour to have been formed by a distended gall-bladder of enormous size. From this, after the operation, the bile had escaped into the peritonæum,

causing intense and universal peritonitis. In making a diagnosis in such a case as this, every thing will depend upon your knowledge of the history and previous symptoms. The circumstances which produce distention of the gall-bladder, you will find upon examination do not bear any distinct resemblance to those which precede or accompany inflammation of the substance of the liver. We may have it from the obstruction caused by biliary calculi, and here you can make a tolerably sure diagnosis. We may have it from disease of the duodenum, or of the head of the pancreas, or from the pressure of aneurysmal tumours in the vicinity. Abscess of the liver is generally accompanied by symptoms of inflammation of that organ, but distention of the gall-bladder does not present any corresponding train of phenomena. There may be some exceptions to this rule, but in making the diagnosis, we must strike a balance of probabilities. The first part of our diagnosis then is this—the occurrence of a tumour in the hypochondriac region, not preceded or accompanied by any of the symptoms which characterise hepatic inflammation. Another important diagnostic, and which I think will apply in several cases, is this. In a case where abscess has formed in the liver, the fluctuation, which is a sign of the existence of fluid, is often preceded by a condition of the part in which there is no sign of the presence of fluid; we have first induration and swelling, and *then the signs of fluctuation*; but this is not the order of succession in the phenomena which characterise distention of the gall-bladder. In abscess we have a hard tumour which gradually softens; in case of distended gall-bladder we have the tumour soft and fluctuating from the commencement. If then we have a tumour in the hypochondriac region, not preceded or accompanied by symptoms of hepatic inflammation, accompanied by jaundice, with a sense of fluctuation from the beginning, and unattended by hectic, the chances are indeed very great that it is not an hepatic abscess, but a distended gall-bladder.

You will perhaps be surprised, that in treating of the diagnosis of distended gall-bladder, I do not lay any particular stress upon position. The reason of this is that the situations in which a distended gall-bladder may be felt are extremely various. First, we may have it appearing in different parts of the hypochondrium, under the cartilages of the ribs. In the next place, we may have it between the cartilages of the ribs and the spine of the ilium. It has been observed by Andral in the iliac fossa, and he has seen it in the epigastric region. In a case which occurred in the Meath Hospital, it presented itself in the epigastrium, a little to the right of the mesial line. Again, in severe cases you may have the whole of the liver filled with bile, and *having a distinct fluctuating feel, not produced by the existence of pus in that organ, but from*

the enlargement of its ducts, which are gorged with bile. In one case mentioned in the Medico-Chirurgical Transactions, this curious circumstance occurred. So far, then, as diagnosis is concerned, position appears to be of very little consequence; but when we have this, in addition to the other circumstances mentioned, it will tend to give additional certainty to our diagnosis. In all cases on record where there was distended gall-bladder, the patient laboured under jaundice, except in that which I have detailed in the early part of this lecture, but perhaps if our patient had lived longer, he would also have jaundice.

There is one disease more which may, and has, I believe, been confounded with acute hepatitis and abscess of the liver. This affection, which has not been sufficiently noticed by authors, is inflammation and abscess of the abdominal parietes over the hepatic region; and this is a very singular disease. It is sometimes trifling, but I have seen a patient die of it. With the original nature of this disease I confess that I am not at all well acquainted; nor can I say whether the inflammation first attacks merely external parts, or whether it is a primary affection of the liver, and that the external parts take on diseased action from sympathetic irritation. In such cases, we frequently observe many of the symptoms of inflammation of the liver, as pain, tenderness, biliary derangement, foul tongue, and morbid stools, with a tumefied state of the integuments. After these symptoms have continued for some time, the tumour increases in size, becomes softer, and matter forms. You give exit to the pus by opening the abscess with a lancet, and the patient gets well. This occurrence I have frequently witnessed. From a consideration of all the circumstances, it strikes me that in this disease the first morbid action in all probability commences in the liver itself, and that the external inflammation is an example of the strong sympathy which subsists between disease of deep-seated parts and the integuments which cover them. Of this fact you have several illustrative instances. In pleuritis we frequently find the integuments of the chest remarkably tender on pressure; and in cases of inflammation of the brain the integuments of the scalp have their sensibility much increased. The same thing occurs in hepatitis; and in this disease one of the first distinct symptoms is this tenderness of the superincumbent skin. Now, you can conceive that if this morbid sensibility of the investing parts should increase, that in place of having some pain and tenderness accompanied by swelling, we may have suppurative inflammation set up in these parts; and that, under such circumstances, the inflammation may leave the internal organ where it first existed, and be thrown upon the external parts in its vicinity. It strikes me that this is not unfrequently the case in this curious affection. In the case of this disease which I have seen:

prove fatal, the following circumstances were observed:—evident symptoms of inflammatory fever; pain and tenderness in the region of the liver, followed by the appearance of a tumour, which became fluctuating, was opened, and a quantity of matter discharged with considerable relief to the patient. She left the hospital, but returned again in about a fortnight or three weeks, with an enormous tumour in the same place, which was again opened, and a vast quantity of purulent matter evacuated. Though the matter continued to flow out freely, she did not recover strength; and on inquiry it was found that, before her second admission, she had spit up some blood. One day, while dressing the abscess, the gentleman who attended her observed that when she coughed, air passed out through the wound, proving the existence of a fistulous communication with the lung. On examination after death we found an abscess, the base of which rested upon the peritoneal surface of the liver, without engaging its substance. From this the matter had made for itself a double passage, one externally, the other through the diaphragm and pleura into the substance of the lung. This was the only case in which I have seen this disease prove fatal; and in it death appears to have been caused by the extent of the disease, and by the abscess opening into the pleura and lung.

CLINICAL LECTURES

DELIVERED BY

G. J. GUTHRIE, ESQ., F.R.S.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS, &c. &c.

At the Westminster Hospital.

LECTURE XIII.

On the Division of Strictures.

GENTLEMEN,—A stricture is said to be impassable when an instrument cannot be passed through it, although there is still a sufficient channel open for the evacuation of urine, which trickles through in an insufficient and incomplete manner, giving rise to those symptoms of inconvenience and distress which have been already enumerated. It is said to be accompanied by retention or suppression of urine when the stricture is so complete that nothing or only an occasional drop of water can be forced out. Under these circumstances different methods of treatment may be had recourse to, the selection or choice depending principally on the degree of difficulty experienced in the transmission of the urine.

The terms *suppression* and *retention* of urine are commonly and indifferently used to express an incapability of making water, although technically they imply two very different states, suppression being that in which no urine is secreted by the kidneys, retention denoting only

the impossibility of evacuating it from the bladder, in which it is retained in a compulsory manner. The degree of danger is not less different, although it is urgent in both; but it can be always removed in retention by a surgical operation, whilst it is often impossible in suppression to give relief by any hitherto known means.

It is not my intention to notice those suppressions of the secretion of urine which have been related by various authors to have occurred, as it were, spontaneously in individuals of peculiar constitutions, and in which some compensatory discharge took place from one or other of the various surfaces of the body, but merely those which are directly connected with the present subject. A great operation performed on any part of the body, such as an amputation, will often give rise to a suppression of urine for twenty-four or more hours, but this is usually obviated by opiates and diuretics with antispasmodics, in moderate but repeated doses; although when the patient has died from exhaustion, or the super-added shock of the operation, it has never been removed. It may occur from more trifling causes. I once laid open two fistulæ in perinæo of small extent, and without much difficulty, or almost any hæmorrhage. The patient had made water just before the operation, and was seized, four hours after, with a cold fit attended with shivering, of which he thought nothing. It lasted twelve hours, and was followed by a hot fit, in which he died, in less than twenty hours after the little operation was performed. I examined the head, chest, and abdomen, but could find nothing to account for his death. There was no water in the bladder, nor had he passed any after the operation.

When the urethra is pervious, the fact of the suppression is of course easily ascertained by the catheter, and the nature of the case is so far understood; and, as the bladder may, from paralysis or from over distention, have become incapable of discharging its contents, the instrument should in all cases be passed, in order to verify the fact of there being no urine in the bladder. The cause of the suppression must be then strictly investigated. If dependent on alarm, it must be removed by the means indicated; if attributable to inflammation of the kidney, bleeding and proper antiphlogistic means must be resorted to; and if it should depend on obstruction, the nature of it must, if possible, be ascertained, or relief cannot be expected. As one kidney is sufficient for the purpose of secretion, a suppression of the secretion in one kidney, or an obstruction in one ureter, will not be a positive cause of death, regarding it only as an obstruction; and I am not aware of any means of cure applicable to suppression from disease on both sides, unless such as nature may herself adopt. I have mentioned an instance in which disease of the uterus, extending to and surrounding both ureters, led to a suppression of

the secretion, and death; but these causes are rare; and the particular ones to which your attention is especially required are those connected with the bladder. I have said, that when the bladder is forcibly dilated by the obstruction of the urethra, on the one hand, and the secreting power of the kidney on the other, the peculiar mechanism at the orifice of the ureters is brought into action to prevent mischief, by compressing the neck of their orifices, and thus preventing, or nearly preventing the flow of urine into it. A suppression of the secretion is the consequence, and thus, if a person could survive long enough, he would die of the suppression of urine in all such cases, giving rise to low fever, coma, and death, or to paralysis, or sudden death by apoplexy. The urethra always, however, yields, and the retention as well as the suppression are relieved; but, as the urethra does not yield for many hours, and in some cases in which it is not diseased and is capable of undergoing a high degree of irritation for two or even three days, time is allowed for surgery to give relief, if its art and science are properly applied.

The question of time depends on the previous as well as on the present state of disease, and requires decision in execution as well as judgment in consideration. When the patient has suffered long from disease of the urethra with obstruction, and the bladder is very much thickened, it cannot dilate so as to hold any considerable quantity, and all the most violent and distressing symptoms may arise from ten or twelve ounces of water as readily as from two or three pints, and in twelve or eighteen hours as well as in six-and-thirty, or in three days. The size of the bladder being but little augmented in this case, offers no assistance to the judgment: it can scarcely in fact be felt either above the pubes or through the rectum; and it is on the agony of pain experienced by the patient, and the state of constitution as expressed by his appearance, and the general symptoms, that the practitioner must depend as his guide. In such a case the patient will rapidly be exhausted, and irreparable mischief will be done to the parts or the constitution, unless relief is early obtained by a surgical operation. Judgment in discrimination and decision in action are here two most valuable qualities in the surgeon; and as soon as he sees that the patient is not likely to be relieved by more simple remedies, he ought not to wait until the danger is so far augmented that he has not a moment to lose, or until great mischief is done, but proceed whilst there is still time, and the system is but little impaired by the attack, to do that which must perhaps be done at a later period, when it may be useless. Fifteen and eighteen years ago I was in the habit of seeing much more serious cases of this nature than at present. The surgery of these parts has been much improved, and relief is sought for and given so much sooner than formerly, that the same number of bad cases

are not now met with. No operation that can be performed or attempted can do half the mischief that will inevitably follow a rupture of the urethra, and an extravasation of the urine into the surrounding parts, whilst it also saves the constitution at the moment, and may also be the means of effecting a permanent cure, or at least a great alleviation of the evil. The question of time, then, must be one founded on many observations made by the bedside of the patient. I shall say to you, as a guide, as I have said to you in strangulated hernia, the operation had better be done a little before it is absolutely necessary than a little afterwards; and I beg of you to remember, that these cases only, and very rarely occur, except in persons who have had strictures for a series of years, and which have long been to them a source of great misery and danger. In all other instances I may confidently state to you, as a general rule, that operations are never necessary, they being relievable by more simple means.

In the management of common cases of retention of urine, a difference of opinion exists among the best surgeons of the present day; some making a marked distinction in their local treatment of those which appear to have occurred from the supervention of inflammation, and others not. This relates principally to the use of the catheter; the phlogistic surgeons deprecating its use until the inflammatory symptoms have subsided, when it no longer appears to be necessary. The other party, of which I profess myself to be a great supporter, use the catheter as a means of reducing inflammation, as an anti-phlogistic measure.

If a young man who has been long suffering from gonorrhoea, the inflammation of which has extended to the back part of the urethra, goes out, and exposes himself to cold after drinking a quantity of champagne, iced punch, &c. &c., he often finds himself unable to make more than a few drops of water, or even to make a single drop, although the desire to do so is most urgent. That the inflammatory affection of the urethra has been augmented no one disputes, but many recommend that in such cases the patient should be bled, put into the hot bath, that an enema should be administered, with calomel and opium, &c. &c., before the catheter is used. I hear this continually said by men of great experience in the profession, and, however much I may respect their opinions generally, I cannot but think they are in error. Relief is at last obtained by these means, it is true, but not until after much suffering; whilst the catheter, when used at once, takes off the irritation of the bladder, and removes the spasm, or irregular action of the muscles surrounding the urethra. When the bladder is quieted by the evacuation of its contents, the other remedies may be more advantageously employed, and will require to be carried to a much less extent. The catheter in such a

case need not be of the very smallest size; and although a gum elastic one is the best, a silver one will often answer very well; and if one is not at hand, a common bougie may be passed gently through the urethra, and allowed to remain for a few minutes, when the patient should be desired to make an effort as it is withdrawing, when the water will be found to flow.

A tradesman came to me yesterday evening, suffering from great irritation in his urethra, with an incapability of passing his urine, except by drops; he had been taking cubebs in large doses, and had exposed himself to cold. I advised him to be cupped on the perineum, to take a dose of physic, a hot hip-bath, and to go to bed. He returned to me this morning, saying that he could not pass a drop of water, and that he was suffering great pain, with a sensation of bursting. I immediately passed a No. 4 silver catheter; it went into the bladder without the slightest hesitation, and drew off two-thirds of a chamber-potful of water. What would bleeding have done?

Suppose, now, that the patient has a stricture, the nature of which you are acquainted with; say that it will admit a No. 4 bougie, that it has been irritated by attempts to pass a larger one, or from any other cause, and the patient cannot make a drop of water. This is a case in which inflammation has supervened from violence, and the person will be in great distress, which will remain undiminished for hours under any other treatment than the passage of the catheter, which will at once give him relief, and a No. 2 or 3 will often pass with ease in this kind of case, although scarcely a drop of water can be made.

When you are unacquainted with the state of the urethra, and know nothing further than that the urine has been evacuated with difficulty, or in a very small stream, you will often be foiled in your attempts to get into the bladder, and you must then have recourse to general means, in which case it is said you have added to the mischief which already existed; but I am not satisfied that you have done so if you have proceeded with that caution and gentleness which are necessary, and which I have so strenuously enforced throughout my observations. The patient is also better satisfied, and he submits with more patience to the delay and misery he must endure before he can obtain relief, whilst if you succeed he at once says he is in heaven. If the obstruction is in the first five inches, or from that to five inches and a half, take a very small straight gum elastic catheter, and try it with and afterwards without a stilet, bringing the urethra well forward as you introduce it, until it is quite upon the stretch. By varying the motion of the two hands the point of the bougie may be applied to every part as nearly in succession as possible, with the hope that it may find the opening. If it should do so, it passes on to the bladder,

and the patient is relieved; but do not withdraw the catheter; the smaller it is, the greater the necessity for leaving it there. The general symptoms will not be increased by it, or if they are, they may be subdued by general means. The eyes of the catheter should be introduced so far into the bladder that they may not irritate its neck; and if the bladder itself should be so irritable as to render its presence very distressing, it may be withdrawn from the bladder, and yet retained in the urethra just beyond the stricture, ready to be passed onwards if required. This is, however, rarely necessary, for the urine flows readily by the side of it if the catheter be kept through the stricture. In two or three days the size of the catheter may be increased, and so on until the cure be completed, or the urethra restored at least to its natural dimensions. I once, some years ago, introduced a small catheter into the bladder of a gentleman in a case of this kind, and gave him instantaneous relief, but unfortunately withdrew it. The retention of urine did not return, but he made his water with great difficulty, and it was three months before I could again hit the opening and commence the cure. The passage of a bougie or catheter often, however, causes all this mischief, as I have already stated, and it may then be its own cure by being retained in the part. A medical friend of mine has had stricture for some years, for which he has been treated by caustic in Paris, and by other means in other places, without effecting a cure: latterly the stricture has become very narrow, and every touch or application to it of any kind whatsoever was sure to bring on a paroxysm of fever or a fit of retention of urine, which lasted several hours, so that at last he dreaded its being touched in the gentlest manner. I assured him that all this evil arose from the urine passing over the irritable surface of the stricture, and that he must keep the catheter in so as to prevent its occurrence. This he did, and as the instrument was of the smallest size, the urine soon flowed by the side of it; a larger one was introduced, and in this gradual manner the irritability, both of the stricture and of the bladder, have been overcome, and he can now pass a No. 8 and his water at all times with ease. When the catheter appeared to irritate the bladder, he partly withdrew it, and after the first two increases of size, he used only a hollow gum bougie, which went just beyond the stricture, in a manner I shall hereafter notice.

When the obstruction is beyond five inches and a half, or is at the curve of the urethra, the small gum catheter should be also made to take a proper curvature; and as it is so small that it can have but little stability, I usually try it with the wire in it, which even then only gives it a moderate degree of firmness. When a larger one is used, and by having been retained on a wire for a long time it keeps its curvature, it may be used

without; but it does not appear to me to be so manageable an instrument, as its point cannot be retained so readily against the upper surface of the urethra, or directed so easily to any particular part. It may, however, gain, on the other hand, from its flexibility, and the surgeon should have both kinds ready for use. If, after several careful and steady attempts, the gum catheter fails, a small catgut bougie may be tried; if it can be made to stick in the stricture, it will soon soften and swell, and dilate the anterior part of it; and as the whole of a stricture relaxes on the dilatation of a part, the urine may, and often will, flow on the bougie being withdrawn, particularly if it be done during an effort to evacuate it, by which act it is forced against the back part of the obstacle.

If the catgut bougie fails, a common plaster one may be used in a similar manner; if a catgut is not to be obtained, recourse must be had to the silver catheter, and the surgeon should be provided with them of two or three different curvatures, from that I have described to one much less bent, for one will often proceed when the other will not; they should have a pure tin stillet, and a wooden handle with eyes, and be about ten inches long. This instrument is to be passed slowly and steadily down to the stricture, the patient either standing or lying on his back, as may be consonant to the usual practice of the surgeon. The catheter must not be too large, or it cannot go through, and if too small at the point it will easily take a wrong direction, and make a false passage, if undue force be applied. The point of the instrument, when it reaches the stricture, should be pressed against it, in order to ascertain the distance; it should then be directed against the lower part of the urethra, and then against the upper, with the view of obtaining a sufficient estimate of its situation. It should then be withdrawn an inch, when the parts being put fully on the stretch, it should once more be passed onwards, the point being borne against the upper surface of the urethra until it reaches the obstacle, into which it may perhaps, by gentle pressure, be insinuated. The French surgeons have been in the habit of using a sharp-pointed conical catheter, which they forced through the stricture, or something else, and frequently got into the bladder in this way; but this plan should never be resorted to. It cannot be doubted that some force is necessary, because pressure is force, however gently it may be applied, and men have different ideas of what is or is not gentleness; but a very little practice soon teaches a surgeon what is the extent of it, in the shape of pressure, which he may use without the risk of tearing the urethra, and the sooner he acquires this knowledge the better, because beyond that he must not go. This gentle degree of pressure must be continued for several minutes, until the instrument passes on, or the incapability of overcoming the resistance by fair means is obvious.

If the urethra is torn the mischief is increased, for the instrument will always take that course; but a little bleeding is not a sign of laceration, for the stricture is very vascular as well as sensible, and blood readily flows from a very moderate examination, even without pressure. A surgeon cannot tell what another has done who has preceded him; but he must know when the urethra has yielded from laceration effected by his own hand. The best directed efforts having failed, the patient, if a vigorous man, should be bled from the arm; he should invariably be cupped on the perineum to the utmost quantity that can be got, and which rarely exceeds twelve ounces, or a dozen or twenty leeches may be applied in relays, so as to keep up a constant drain from it, and which bleeding may be encouraged at intervals by the hot hip-bath, or, if the patient wishes rest, by an evaporating bread and water poultice. The bowels should be evacuated by a large enema of salts, gruel, and castor or other oil, repeated from time to time, if necessary, until the rectum becomes perfectly clear. Opium is now to be administered, sixty minims or a drachm of tincture of opium are to be put into two, but never more than three ounces of gruel, or warm water, and injected into the rectum. The quantity is small that it may be retained, which would not otherwise be done, if it were larger. Batley's solution of opium or laudanum are also to be given internally, twenty minims for the first dose, and ten for the succeeding ones, every hour or two hours, as may appear most proper to effect the object of bringing the patient quickly under its influence. It is contended by some that opium introduced into the rectum acts more powerfully than when taken into the stomach, but it has not been the case under my observation, and I always calculate that double the quantity is the proper dose, whether it be used in the fluid or solid state. When the patient is fairly under its influence, and the cure is to terminate favourably, the irritability of the bladder diminishes, the urgency of the calls to make water are neither so severe nor are they so frequent, the patient slumbers for a few minutes between them, a state of general relaxation takes place, and a few drops of urine follow each other more rapidly than formerly, soon to be succeeded by a small but uninterrupted stream, after which the patient dozes or falls asleep, and is only awakened to obtain perfect relief by emptying, or nearly emptying the bladder.

The effect of the first or large purgative enema is sometimes great; it brings on the due consent between the parts, and often gives rise to complete relief. If it does not quite do it at once, the opiate injection generally completes it. Purgatives, therefore, are valuable aids, and many persons liable to slight attacks of retention, have recourse as soon as they begin to feel a difficulty in passing their water, to a good stiff dose of salts and senna and manna, and a hot-bath, which usually

give the required relief. The hot-bath is a very great assistance in many cases, and is useful in all. I always, however, recommend it much hotter than is commonly done, at 100 to 104, or as hot as the patient can bear it, and he should remain in it until he is quite faint.

These various means must be continued and repeated, although in vain, until it is obvious that they are inefficient, and that relief must be obtained by some other and more strictly surgical proceedings. The urine may perhaps drop from the urethra, the patient may be able to collect and show half or even a whole wine-glass full, the bed-clothes may be wet from it; but this will not do; it is not that sort of evacuation which is absolutely necessary to give relief. The kidneys secrete more than is discharged, and are willing to secrete still more, if the pressure on them which prevents it were taken off. The bladder is distending in spite of this stillicidium, and the rupture of the urethra is at hand. The agony which the patient endures is great, the anxiety of countenance is strongly marked, the general distress, the great sympathy of the whole system are too fearfully expressed to be mistaken. The bladder may be felt, rising high above the pubes, and descending into the rectum, if it has been capable of dilatation, and the surgeon has only the choice of his operation left. Four are recommended by different modern authors:—1st. To puncture the bladder above the pubes; 2nd, through the rectum; 3rd, to open the urethra from without; 4th, to divide the stricture by an instrument passed along the urethra.

The operation above the pubes is dangerous, inasmuch as an extravasation of urine may readily take place after it, and lead to the formation of matter and other evils of serious magnitude; it should never, therefore, be had recourse to in cases of retention of urine from stricture. The operation through the rectum is easily done, and is not liable to the same objections, except in the case which cannot be foreseen, of the peritonæum descending between the bladder and rectum lower than is usual; I may say, except in some particularly rare instances which scarcely form exceptions to the general rule. It is, therefore, the operation which is to be preferred by those who are unacquainted with the anatomy of the parts in the perinæum. The best mode of doing it is to cause the patient to lean over the side of the bed, when the fore-finger can more readily be introduced into the rectum until it touches the prostate through it. The posterior boundary of this being distinguished, the curved trocar and cannula are to be introduced, the point of the trocar being withdrawn under cover of the tube until the end of it rests by the side or under the fore-finger a little beyond this part, and about or rather short of the middle of that which is called the triangular space. The trocar is now to be advanced, and it and the cannula carried steadily into the bladder, when the trocar is to be

withdrawn, and the cannula pushed in so as to secure a free evacuation of the urine. The cannula may now in turn be withdrawn, as its remaining would only cause irritation, and be of no use, for the opening from the rectum into the bladder will always remain open until the canal of the urethra becomes pervious. There is more danger that it may never close, but become a fistulous opening, than of its closing too soon; and this is another and the principal objection to the operation. It is also urged against it, that the disease in the urethra is not removed; but it must be clearly understood, that the disease in the urethra is much more manageable when the pressure upon it of the bladder is taken off, and may in my opinion be almost, if not always, successfully treated, and the canal cleared or rendered pervious in a short time afterwards, by permanently placing an elastic hollow bougie in it in the manner I shall presently indicate. This is therefore the operation, I repeat, which is always to be selected by surgeons who are not conversant with the anatomy of the perinæum; but I do not say it is the best for those to select who have a greater degree of knowledge.

The operation of opening the urethra from the perinæum in cases of retention of urine may be a simple one or otherwise, depending principally on the situation of the evil. If the stricture be anterior to or at the commencement of the bulbous part of the urethra, nothing can be more easy for any one to do; and the facility with which it can be done in this situation has led to some misconception with regard to the operation generally. Sir Astley Cooper, who claims the introduction of it into the practice of surgery, directs a sound to be passed down to the stricture; the point of it is then to be turned downwards, and an incision made upon it and beyond it. If the stricture is a narrow one, the dilated urethra behind it will be brought into view; or, if otherwise, it is to be sought for and opened, when the urine will be evacuated, the patient immediately relieved, and time given to treat the stricture itself, which, as I have said, after the puncture through the rectum, is much more manageable, in consequence of the forcing of the bladder against it being removed. In the first case in which he did it, in the year 1793, he merely made an incision through the common integuments, when the dilated urethra came into view; this he opened with a lancet, allowed the urine to escape, and the patient was soon cured of his disease. If things were always as simple as this, a very few minutes' consideration would suffice. But this is not the case: and it is admitted by the ablest surgeons that when the disease is situated at the termination of the bulbous portion of the urethra, or in the commencement of the membranous part,—and it is not easy to say what a long-continued disease may not do by extension to the neighbouring parts,—the operation is often exceedingly difficult: it is

more particularly so when it is attempted by making an incision on the left side of the raphè of the perinæum, nearly in the same manner, as in the operation for the stone. From the stricture preventing the passage of the catheter, the information to be gained from its presence in the urethra is wanting; the hardness and derangement of the soft parts, which in these cases has often taken place, adds to the difficulty, and the urethra behind may not be sufficiently dilated to make it very tangible, so that it is not so easily found, rendering, in many instances, the operation one of great difficulty, and deterring, therefore, many persons from doing it or any other. In most cases the urethra behind the stricture only is divided; and where the operator is determined to carry his catheter on into the bladder, it is probable that he does not always divide the strictured part of the urethra, but carries it on by the side of it, establishing, perhaps, a false passage at the part, which will for the time, take the place of the original one, and which will also, it is probable, lead subsequently to a recurrence of the evil.

The improvements which have been of late years made in the practice of surgery render this operation less necessary than formerly; cutting out, or cutting into, portions of the urethra, which I have seen attempted, are, like cutting out testes, comparatively obsolete operations; but still, an opening into the urethra may occasionally be required; and when the disease is situated at the termination of the bulbous portion of the urethra, or even further back, I recommend the operation to be done in the following manner, as much the most simple and certain:—The patient being placed and secured, as in the operation for the stone, a catheter or sound is to be passed down to the stricture, and held steadily against it, the concavity being as usual upwards, the point directly applied to it. The rectum having been previously cleared by an enema, the fore-finger of the left hand, duly oiled, is to be introduced into it, and the membranous part of the urethra and the prostate are to be examined, as well as the bladder, the state of which will, in all probability, have been previously investigated. If the membranous portion of the urethra is dilated by the urine, so much the better; but the object of introducing the fore-finger is to ascertain the relative situation of the upper part of the rectum and the urethra, which latter part only touches, or is nearly in direct application to, the rectum, at the termination of its membranous part and the commencement of its prostatic portion. There is a certain distance, which is greater or less in different individuals, between the last inch of the rectum and the urethra placed above it. The two parts form two sides of a triangle, the apex of which is the prostate, the base the external skin. It is within the two lines of the triangle that the operation is to be done. The surgeon, taking

the catheter in his right hand, whilst the fore-finger of the left is applied to the upper surface of the rectum, moves the point upwards and downwards, so as to communicate with the fore-finger of the left hand, and to convey to it a knowledge of the situation of the extremity of the instrument, and particularly of the distance between them, and which the motions given to the catheter by the right hand will clearly indicate. The thickness of the parts between the obstruction and the rectum can be estimated with sufficient accuracy, both at the point where the left fore-finger is applied, and at the surface of the skin; for, although the membranous part of the urethra cannot be easily felt from an incision made on the left side of the perinæum, it can always be distinguished from the rectum. The next step of the operation is to divide the skin, cellular membrane, fascia, muscular and tendinous fibres, which may intervene between the upper surface of the rectum and the under surface of the anterior and middle portions of the membranous part of the urethra. This is to be done by a straight, blunt-backed, narrow, sharp-pointed bistoury, fixed in its handle; and there are two ways of commencing the operation: the first, when the obstacle is behind the bulb and the external parts are not diseased, may be done by a straight incision, in a perpendicular direction;—indeed the operation may always be done so, if the surgeon is well acquainted with the anatomy of the parts; but if he is not, or they are very much hardened, and consequently unyielding, a transverse, curved, or crescentic incision should be made across the perinæum, the centre of which corresponds with the raphè, and is one quarter of an inch above the verge of the anus, or as near that distance as may be, with due respect to the rectum. This gives room, and allows the parts to be separated as much as they will admit. If the transverse incision is not had recourse to, the point of the straight bistoury is to be placed on the skin a little above the verge of the anus, the cutting edge being above, the blunt back towards the rectum, the handle being a little depressed, the point a little inclined upwards. The degree of inclination necessary to carry the knife inwards for the distance of an inch, and clear of the rectum, will be indicated by the finger in that part, and the eye of the operator will correspond with the point of the fore-finger, so that the bistoury may be steadily pressed in to that extent, and then be carried upwards, and brought out in the exact median line, making an external incision of at least an inch and a quarter to an inch and a half, as regards the external parts, and which may be then extended as space is wanted for the prosecution of the operation. The part being sponged, the surgeon again introduces the bistoury in the median line, the point being directed upwards and backwards towards the urethra, and he may then deepen the cut. The fore-finger

in the rectum will always tell him where the back, and consequently where the point of the bistoury is. The opening will now be sufficiently large to allow the operator to lay aside the knife, and to feel for the urethra with the point of the fore-finger of the right hand, an assistant keeping the catheter steady against the stricture, the end of which will now be readily felt. If the point of the fore-finger of the right hand does not go beyond it and touch the sound part of the urethra, which is dilated by the urine in the generality of cases, the knife is to be resumed, and the fore-finger being withdrawn from the inside of the rectum, is to be placed in the wound, on the outside of it, and it is to be thus depressed as far back as possible; the back of the knife is then turned to it, whilst the point exposes and opens the urethra, and which it can do very easily at the apex of the prostate, at its transverse portion, at the very back of the membranous part of the urethra; but it is not necessary to go so far back, and the membranous portion may be opened at its middle with every advantage, and with perfect safety to the gut. A good anatomist and surgeon will open the urethra in this way sooner than the mode of doing it can be described, the urine will make its escape and the patient will be at once relieved. Whether the stricture shall be now divided or not, is a question presently to be considered; the cure can be completed either with or without it.

The young surgeon (and I never speak or write for old ones), in order to understand the method of doing this operation, should dissect the perinæum, first in the usual manner, and make himself well acquainted with the central tendinous point, as it is called, to which the transversi perinæi, the acceleratores urinæ, the sphincter ani, and the compressor urethræ muscles are attached. This being divided, and the acceleratores muscles being separated in their median line, they ought to be turned aside, when their deeper structure can be examined as well as the bulb of the urethra which they cover. The sphincter ani muscle, both in its superficial and deep part, should now be carefully investigated, in connexion with the bulb of the urethra and its attachments to the deep perinæal fascia. A side view of the pelvis should then be obtained, and the relative situation of the parts duly estimated, and which a dissection from within the pelvis outwards will confirm and establish in the mind. The most important dissection is yet, however, to be made, and it is to be done by placing the body on the face and raising the pelvis, so that the parts are elevated and made more tense. The sacrum is to be exposed with the edges of the glutæi muscles, the coccyx is to be cleaned, all the loose fat taken away, and the sphincter and levator ani muscles fully exposed from behind. The manner in which the levatores ani cross from side to side to make the funnel-like process usually described, is then well seen, but they make principally the body of

the funnel, leaving a tube extending from it of an inch and a half in extent and sometimes two inches, entirely cut off by it from the cavity of the pelvis; and a student can have no idea of the possibility of cutting away an inch of the extremity of the rectum, or of the safety with which he may divide an inch and a half of it, unless he makes this dissection. It is true that the tube of the funnel, or the gut, is also covered by the fibres of the levator, intermingling with those of the sphincter, but these do not interfere with the view of the subject I have given, as the inside of the levator is lined by a fascia, which is reflected upwards on the side of the rectum, prostate, bladder, &c., which separates these parts from all beyond or below them. The sacrum should be now sawed through and removed, the levatores ani carefully examined and divided in a median line on the rectum. The sphincter ani should be treated in a similar manner, and the whole of the lower part of the rectum exposed. This gut should now be turned backwards, the recto-vesical fascia being divided in a similar manner; this being done, there are still muscular fibres, fasciæ, and cellular membrane to be dissected and divided before the membranous part of the urethra, the prostate, the vesiculæ seminales, the back of the triangular space of the bladder are brought into view, and this dissection is most important and difficult. If the perinæum has not been in part dissected it should be done, and the connexion of the superficial fascia with the deep-seated should be demonstrated. The first and last dissection of the perinæum will demonstrate all the points I have alluded to in the operation, and will also enable the student to prepare himself for dividing the neck of the bladder in continuation, if such an operation should be found necessary.

This is the operation in the perinæum I have performed and recommended for years, but it sometimes happens that the surgeon prefers cutting on the face of the stricture with the view of dividing it, supposing he will have less to do, but in this he will be frequently disappointed. If the stricture is at the posterior part of the bulb he must divide that part to get at it, a thing I believe of no sort of consequence, and leading to no inconvenient result, although the contrary has been asserted. On opening the urethra he finds he is probably half an inch from the stricture, having cut on the point of the catheter turned downwards, this half inch must be divided, and, in fact, a nearly similar operation to that I have recommended must be done, only in a dissimilar manner. When the stricture is exposed a small lachrymal probe may be passed into the canal, I should say in all cases, and the stricture must be divided upon it; but as the urethra at this part descends under the pubes, the surgeon, if not well informed, fears injuring the rectum, within one inch of which he is not, and he begins to hesitate, and to divide, scratch by scratch, or to try and intro-

duce a director by force, and which may and will more easily pass in any direction by the side of the urethra than through it. If he has a very small director he may with a little force pass it over the lachrymal probe, directing it downwards, and thus reach the membranous part of the urethra; the sharp-pointed bistoury may then be run along the director, and be made to cut transversely to each side, then downwards, and lastly upwards if necessary, until a straight or female catheter passes easily into the bladder. If the surgeon has unhappily begun his operation in this way, and cannot get a director into the stricture, he should now introduce the fore-finger of the left hand into the rectum, and having ascertained the relative situation of the line of the rectum and of the urethra, and the incision he has made, the difficulty will be removed by his steadily pressing on the straight blunt-backed bistoury through the stricture, the edge being turned either upwards or sideways, until the urine begins to flow, and his large director can be passed, care being taken to preserve as much as possible the course or line of the canal. In fact he must do at last, after half an hour has been lost, nearly the same operation which I have advised to be done at first.

ESSAY ON THE STRUCTURE AND FUNCTIONS OF THE SKIN.

BY MM. BRESCHET ET ROUSSEL DE VAUZEMME.

Read by the former to the Académie Royale des Sciences, on their sitting, 27th of Jan., 1834.

Rerum natura sacra sua non simul tradit aliud hæc ætas aliud quæ non subibit, adspiciet.—*Senæger Nat. Quest. lib. viii. c. cxxxv, xxxi.*

(Continued from page 306.)

THESE sudoriferous canals are not the termination of the general capillary system, and do not bear any resemblance to that which Bichat has denominated *exhalant*.

Previous to the lecture of the present essay they were never described or observed by any individual, with the exception of Eichhorn, who has spoken of the *sudatory* canals indicating more especially the external orifices of the *hydropherous*. This author states, that they are straight and uncontorted, and asserts the fact of having introduced a horse-hair into their cavity, a circumstance which would appear to prove that he had mistaken a bulb of hair for a sudoriferous canal, or that he had made an artificial one. M. Eichhorn was well acquainted with the functions of these canals,

VOL. V.

but could only follow these tubes as far as the papillæ, without indicating their ulterior distribution. He assigned to them the twofold use of exhalation and absorption, which office appears, at least to us, highly incompatible.

In 1777, Leeuwenhock announced the discovery of the pores of the skin by the aid of a microscope, but the number which he admitted appeared to prove that he saw anything but the external orifices of the *hydropherous* canals.

In fact, the most conciliating imagination can scarcely grant the existence of 14,400 apertures for each square line of cutaneous tissue. We coincide with Blumenbach in the opinion, that Leeuwenhock has committed an error in his calculations. Shaw perceived filaments proceeding from the epidermis to the corpus mucosum, which are easily rendered visible in a state of incipient putrefaction, or on detaching the epidermis with precaution. Dr. W. Hunter has described and delineated these delicate, transparent, elastic, colourless filaments, and considers them as the transpiring canals. Chaussier and Bichat regard them as exhalant and absorbent vessels; Monro, perceiving filaments spirally disposed beneath the epidermis, believed them to be composed of nerves; Hontana speaks of tortuous vessels, without indicating their nature; M. De Humboldt denies the vascular properties of these vessels, and imagines that they depend on the simple duplicatures of the skin.

Gaultier caused the protrusion of the exhalant vessels which proceed from the sanguineous eminences to open externally after traversing the epidermis. He had correctly observed the situation of these orifices between the little excavations which exist on the dorsal aspect of the ridges, where he had remarked the presence of minute drops of limpid fluid. According to his estimation, there exist from four to six of these little excavations on each square line, which is far from the number designated by Leeuwenhock; and he moreover considers that each orifice corresponds to a vascular eminence. Gaultier has, without doubt, considered the nervous papillæ as vascular eminences; and it was in vain that he excited the protrusion of the exhalant vessels from their summit.

G. Prochaska endeavoured to establish the existence of diverse orders of vessels in the

skin; he refers to his third class those which are directed towards the papillæ, some of which terminate in a cul-de-sac, whilst others return to and anastomose together in the net-work. These vessels appear to resemble the exhalants already described, and another class of vessels seems to be formed by the sudoriferous canals; but the expressions of this author induce the belief that he entertained only a superficial acquaintance with these canals*.

The observations of Albinus, Meckel, Craikshank, and those which Humboldt performed with a microscope magnifying 312,400 times the object exposed to its focus, have not advanced the discovery of the cutaneous pores. Seiler and Bécclard have not been more fortunate in their attempts, although the former removed the epidermis by means of a razor, during the time that an animal was exposed to perspiration, whilst the latter infiltrated a portion of integument with a column of quicksilver, nearly equal to an atmosphere. The majority of modern anatomists, not only unwilling to admit the existence of sudoriferous canals possessing external orifices, pretend even that the presence of these canals is not necessary: this, at least, is the opinion of Blumenbach, T. H. Meckel, Rudolphi, Hensinger, &c. Hildenbrandt, however, taking into consideration the existence of exhalation, believed in the presence of these pores upon the surface of the skin, without giving any description of these canals. Schroeter, a common engraver at Leipsic, has given a sufficiently correct delineation of the external orifices of these hydrophorous canals; but the explanations that accompany this engraving prove its author did not possess the slightest idea on the subject. According to the opinion of the celebrated zootomist, Delle Chiaje, the epidermis is formed by the conglomeration of sanguineous globules deprived of their fibrin, this membrane being also completely devoid of apertures†.

It is necessary to peruse the recent publications, in order to obtain a satisfactory notion as regards the perforation of the epidermis and sudoriferous canals. The experiments of

Richhorn relative to this subject, however replete with interest, prove that this distinguished physiologist was mistaken as to the exact distribution of these hydrophorous tubes, for since he does not mention their spiral arrangement, but believes them to be conical, and to possess an aperture sufficiently capacious to admit a horse-hair, it is evident that he has confounded them with the sebaceous follicles.

4thly. Of the organs of inhalation situated in the cutaneous tissue. These canals are placed under the most superficial lamellæ of the rete mucosum of Malpigi, or horny layer, and present the form of isolated radicles dispersed amidst this epidermic horny substance; after frequent anastomoses they penetrate the cutis at the intervals which separate the papillæ, and in the vicinity of the sudoriferous canals. All these little tubes symmetrically arranged, terminate in canals still more deeply seated, and disposed in the form of a plexus. The canals appear to differ from the ordinary lymphatic vessels, since they possess an extreme tenuity; they ramify in a resisting, solid, and elastic substance; they are ruptured with great facility, and hence we are in general obliged to study their anatomical characters from separate fragments observed through a microscope; their colour is white and silvery, and the existence of valve-like folds being perceptible through their parietes, appear to indicate a kind of analogy to the lymphatic vessels or veins. Sometimes they are interwoven, forming a series of loops, and in general they are but slightly elastic.

On examining with a microscope these canals, which we consider as the organs of inhalation, and on comparing them with the sudoriferous tubes, the difference between these two orders of vessels is instantly perceived. The sudoriferous canal is larger, softer, more winding, elastic, and spiral. The inhalant is smooth, shining, straight, or slightly oblique, and its central cavity is intersected from distance to distance by horizontal membranes, or a kind of little diaphragms. On exercising tractions on the horny epidermic layer, these canals tear, and the sudoriferous tubes alone remain, which are capable of undergoing considerable elongation. Another circumstance which might aid in the distinction of these two orders of vessels, arises from the fact that these

* *Disquisitio anato. physiolog. organini. corpore humani*, p. 98.

† *Observazioni sopra la struttura della epidermide umana*. Napoli, 1827.

transparent tubes, comparable, as regards their functions, to the lymphatic vessels, or to the veins, present anastomotic ramifications, which are occasionally in the form of a plexus. The sudoriferous canals never offer these characters.

We have constantly noticed these tubes in the skin of man, both in the white and black race, in the whale, dolphin, porpoise, various ophidren and chelonian reptiles; and in the integuments of numerous fishes.

Whatever may be the colours of the horny tissue, the absorbent canals, the nerves constituting the papillæ, and the sudoriferous vessels are constantly white.

If the existence of these canals cannot be disputed, will the nature of their functions be any longer doubted? From what circumstances do we suppose that they aid in the process of absorption?

If these tubes do not absorb, of what use are they? We do not consider that the difference in structure from the lymphatic vessels can be a sufficient reason to deny them the power of inhalation. The medium which they traverse might explain the difference in the structure of these organs, since we can affirm that every thing which is situated immediately above the cutis, presents a peculiar aspect.

The researches which we have made, on demonstrating thus the true structure of the papillæ, have learnt us the manner in which the sense of feeling is produced. We have been enabled to ascertain that the vascular system, properly so called, does not extend beyond the secretory and papillary organs. We have also learnt that the perspirable matter is excreted by the sudoriferous tubes, and we shall shortly explain the manner in which the horny substance is secreted. In proceeding thus by means of abstraction, we arrive at the conclusion, that the canals which traverse the horny substance, or *rete mucosum*, can only be adapted to inhalation. We can add to this induction that the radicles, or little anastomotic arches of these canals extend as far as the most superficial layer of the epidermis; and since absorption is one of the properties belonging to the skin, we cannot detect in this envelope any other organ capable of fulfilling this function.

But here a difficulty presents itself, and if we could resolve it, we should terminate all

incertitude as to the manner in which absorption is effected. It is important to know the mode in which the canals originated. Are they in the form of a cul-de-sac? Do they present open orifices? If we were enabled to follow the sudoriferous canals to the superficies, and to discover their external orifices, we were not capable of tracing in like manner the vessels of which we speak.

These vessels studied for a long time with patient attention, permitted us to discover only that, towards the cutis, they were continuous with an inextricable plexus formed by similar vessels, and that they prolonged into the horny tissue numerous anastomotic twigs forming terminal loops, and occasionally isolated branches; but as regards their origin, towards the most superficial region of the skin, we could never ascertain if there existed cul-de-sacs or open orifices. We can, however, affirm, that we were not able to distinguish open orifices, and thus they resemble, in this respect, the lymphatic and sanguineous vessels of other tissues considered by a great number of modern anatomists in the mamifere, birds, fishes, and reptiles*.

If it be really and constantly true, as we have seen on the intestinal villousities of man and numerous animals, that these canals are deprived of orifices at their commencement, that which is called absorption is neither a true absorption nor a phenomenon caused by capillary tubes; it is therefore necessary to attribute the performance of this function either to imbibition, or to an endosmosis, as two members of this Academy have already imagined.

5thly. Of the organs productive of the horny substance, or keratogenous apparatus. Little reddish glands are perceptible at the base of the cutis, which examined by the microscope, or common magnifying glass, appear uneven, being wrinkled by sanguineous vessels. They are enveloped by a loose cellular membrane, and situated in the centre of little adipose, transparent, superimposed vesiculi, resembling pearls. From the summit of these glands a canal or tube is given off, which traverses the whole thickness to open itself in the bottom of the furrows which are

* Voyez les ouvrages de Hohnmann, de Panigga, &c., &c.

observed in this situation. This canal is enveloped by a diaphanous cellular membrane which proceeds from the circumference of the gland itself. Capillary filaments are seen to adhere to the tube, and glandular organ, in which we remarked that a rather considerable vessel entered by the base. These canals in general represent a series of regularly disposed columns. Nevertheless, these glands are placed at unequal heights, and communicate together by means of intermediate canals. These ranks of excretory tubes correspond to the length of the furrows; that is to say, that they are perpendicular to the plain formed by the organ which secretes the colouring matter, or pigmentum.

The products of the gland that we have just indicated are a fluid resembling mucus, which rapidly condenses, and constitutes the horny layer, or *rete mucosum* of Malpigi, and the epidermis itself is only superficial lamellæ of this stratified body.

(To be continued.)

Foreign Medicine.

Medical Reform in Belgium.

AN address, signed by many of the medical men in Belgium, and particularly by those residing in Ghent, has been presented to the Belgian Chamber of Deputies. In this address complaint is made of the abuse resulting from the law of the 12th of March, and of the decree passed on the 31st of May, 1818, by virtue of which a medical man, after having passed the numerous examinations which the ordinances of the university direct, and having been declared by competent judges worthy to practice, nevertheless remains all his life subject to the superintendence of a commission composed of seven or eight of his professional brethren, often his equals, sometimes his inferiors in talent, who have the power of subjecting him to the most humiliating control.

The following propositions are submitted as the basis of the law which they require.

1. That all the clauses of the law of the 12th of March, 1818, and of the decree of the 31st of May, of the same and of succeeding years, in so far as they refer to the mode of nomination and the number of members composing the provincial medical commissions as now constituted, be reported upon.

2. That consequently these nominations be dissolved and replaced by provincial medical councils.

3. That these councils be composed of twelve or fifteen members chosen by secret scrutiny, and by a majority of votes, from all the individuals legally exercising throughout the province any branch of the healing art.

4. That the choice of the president, vice-president, and the secretary, be made by the King, upon the presentation of the list of all the members chosen.

5. That the functions of the president, and of the members of the council, be gratuitous, save and except the expenses of travelling. The secretary alone to be indemnified.

6. Half the members of the council to be chosen afresh every three years.

7. That until a new law shall have determined the privileges of the councils, those which have been conferred upon the medical commissions by the law and decree above referred to, be preserved, with the exception of the examinations, which shall remain provisionally.—*Gazette Medicale.*

Medicinal Properties of the *Anthelmia Spigelia*.

(*Herbe à la Brinvilliers.*)

This perennial plant, which is a native of the southerly parts of America, although well known to possess powerful anthelmintic properties, is seldom or ever employed in France or in other parts of Europe. Its medicinal qualities are, however, so highly estimated in the Antilles and in Martinico, that nearly all the natives administer it, and the physicians there prescribe it with the greatest confidence. It is probably in some measure attributable to the great difficulty met with in obtaining the fresh plant, and to the improper mode of preparing the syrup, that it has been so long neglected as a therapeutic agent in this part of the world; for, according to M. Noverre, when properly prepared, it possesses over many of the other vermifuge medicines the following marked advantages:—its action is always efficacious; it is agreeable to the taste, and is taken by infants without repugnance; acting as a sedative, it calms the nervous symptoms, which are frequently complicated during infancy.

with worm affections; it does not cause those inflammations which so often accrue from the use of other anthelmintics. One singular effect of this medicine is occasionally to produce an amaurosis, or dimness of vision, which is, however, transient.

The manner of preparing the syrup in Martinico is to boil ten pounds of the plant in six pints of common water for one hour; then, after allowing the plants to remain in the decoction for eighteen hours, to strain, and to add ten pounds of white sugar. The dose is three spoonfuls for an adult, and one for an infant of about three years, each day.

M. Noverre assures us that, although he has been in the constant practice of using this medicine for more than thirty years, yet he has never witnessed any bad effects result from its employment; and he therefore concludes that, although it is a poison, yet its injurious properties have been much exaggerated.

Solanine.

This substance, already found by some French chemists in the *solanum nigrum*, in the *solanum dulcamara*, in the *solanum mammosum*, and in the *solanum verbacifolium*, has lately been extracted from the buds of the potatoe by M. Otto, of Brunswick. He has obtained this alkali by treating the buds with water, mixed with sulphuric acid, separating the sulphuric and phosphoric acid, and the extracted matter, with acetate of lead, saturating the liquid with a preparation of lime, boiling the precipitate in alcohol, and purifying the product by many solutions in alcohol. Experiments made by M. Otto upon two rabbits to prove the action of *solanine* on the animal economy, have apprised him that this substance ought to be arranged amongst the acrid narcotic poisons. One grain alone of the sulphate of solanine destroyed one of the two rabbits in six hours; the other died at the end of nine hours after taking three grains.

The paralytic action which it exercises upon the posterior extremities of animals is very remarkable; for, if horned beasts be fed with the washings accruing from the buds of the potatoe, this kind of paralysis will be produced.

The substance under consideration is white, pulverulent, and restores to a blue colour

turnsole paper reddened by acid. Most of the salts obtained from it take, on desiccation, the appearance of a mass-like gum. The sulphate alone does not.

Improvements in the Parisian Hospitals.

March 22, 1834.—A meeting of the physicians and surgeons of the hospitals of Paris took place yesterday for the purpose of appointing a commission of seven members to draw up a report upon the improvements which can be effected in these institutions. Amongst the members of the commission are MM. Baron, Gueneau de Mussy, Louis, Roux, &c.

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, April 5th, 1834.

MR. BURNETT in the Chair.

Inaccuracy of the Minutes—Stormy Debate—Monstrosities—Torsion—Injection of Air into the Veins—Wounds of the Intestines.

THE minutes of the preceding evening having been read,

Mr. Hunt rose to express his dissatisfaction that the observations on the falsehoods of the Medical Gazette, which formed a great portion of the last evening's discussion, should have been so entirely omitted by the Secretary in his report, it being only stated, that no conclusion had been arrived at; such was not the fact, and he therefore thought it would be wrong to allow such errors to pass by without some notice being taken of them, and begged to move, therefore, "That the report of the Secretary of last week be omitted."

This motion was seconded by Mr. Dewhurst.

Mr. Costello thought that the object of Mr. Hunt would be obtained by requesting the Secretary to state his reasons for altogether omitting the account of what took place.

Mr. Burnett said it was free for any gentleman, who considered the report as inaccurate, to raise objections to what was incorrect, or omitted, but he did not think that the Secretary was necessarily called upon to answer, or explain, his motives.

Dr. Ferguson wished to ask if the Secretary

had any notes of those proceedings; he did not think that the blame rested upon the Secretary, but that there was a controlling power behind the scenes (*loud cries of hear*), and if such was the case their officers no longer belonged to the Society but to some particular party.

Mr. Dewhurst wished to know if the Secretary was or was not *ex-officio* an officer of the committee?

Mr. Greenwood expressed his opinion, that the committee had more than once shown a disposition to act rather wide of the question (*loud cries of chair, chair*).

Mr. Quain proposed, as an amendment to Mr. Hunt's resolution, "that so much of the minutes as referred to the attack on the honour of the Society be referred to a committee."

Dr. Epps said the Secretary had certainly shown a want of duty in omitting the report; but that gentleman was a man of peace, and he felt convinced that such omission had been made entirely through amiable motives.

Many and angry were the speeches which succeeded, and loud were the calls for explanation, when

Mr. Turnham, no longer able to keep silence, rose from his seat and exculpated himself by stating that, on previous evenings, when matters, unconnected with science, had formed the subject of discussion, he had been requested by the committee to "curtail of their fair proportions" all speeches thereunto relating; it was from this suggestion that he had, in the present instance, made such omission.

Mr. Quain called upon Dr. Ferguson for an explanation of his remarks upon the hidden cause of the omission in the minutes.

Dr. Ferguson acknowledged that, in saying some party behind the scenes, he meant the committee: in supposing this, however, he had not attributed any improper motive to them, and he trusted that he should be exonerated from any such intention.

Mr. Costello bore a willing testimony to the accuracy which had in general characterised the reports of the Secretary; he was glad to hear that he had not acted in this instance from any suggestion of the Committee, and he trusted that the matter would now terminate.

Some farther angry discussion ensued, but suffice it to say, a resolution to the following

effect was finally proposed by Mr. Salmon, and carried:—

"That the attack upon the honour of the Society, which was under discussion last evening, be considered unworthy of notice."

This resolution was unanimously carried.

Mr. King related a rare case of deficiency in the muscular parietes of the abdomen.

Mr. Hunt said he had heard a lecture some years since given upon a monstrosity of this kind, but upon viewing the child the alleged deficiency proved to be an enormous umbilical hernia.

Mr. Costello was well aware that the absence of this part of the abdomen was one of the characteristic signs of a certain period of fetal life; it was one of the stages through which the fetus must pass, and these cases could only be explained by supposing that the development of this part of the body had from some cause or other been arrested.

Mr. Quain said the state of the abdominal parietes, mentioned by Mr. Costello, was not so uncommon, and was very different from that mentioned by Mr. King, there being in the latter no deficiency of integuments.

Mr. Dewhurst said a similar instance had been mentioned in the *Lancet* some years since.

Dr. Jewel wished to ask Mr. Costello or Mr. Quain, if they had ever met with any instance of total deficiency of the eyes.

Mr. Johnson referred Dr. Jewel to a work on monstrosities, published in Germany, wherein mention was made of such occurrences.

Mr. Costello then exhibited a pair of forceps for performing the operation of torsion, which he had just had made.

Mr. Simpson wished to know the fate of the patient who had been operated on by Mr. Costello, some weeks ago for torsion, before the Society.

Mr. Quain stated that the animal had fallen a sacrifice to the cause of science, but not from the operation then performed; some gentleman, more chemically than surgically inclined, had administered a dose of poison to the animal, and had succeeded most cleverly in terminating its sufferings.

Some farther interesting remarks on torsion, and injection of air into the veins of animals, having been made,

Dr. White related a case of rapid recovery from a large wound of the intestines and walls of the stomach.

After which the meeting separated.

ROYAL INSTITUTION.

It is with great pleasure we state that Mr. Fuller has bequeathed the sum of 10,000*l.* to the Royal Institution. Alas, how different is it with medical science! For this there is no patronage or encouragement,—no prizes offered, except the paltry one of 10*l.* by the Royal College of Surgeons, with its 10,000*l.* a-year. The College of Physicians, from bad policy and selfish by-laws, is so poor that it is scarcely in a position to maintain an establishment; while the Apothecaries' Company, with an immense income from the sale of licenses, between 5,000*l.* and 10,000*l.* annually, does not offer a prize of 5*l.* for an essay on pharmacy, though this branch is one hundred years behind its actual condition in other European nations.

THE LONDON UNIVERSITY HOSPITAL.

At the late dinner of the friends of this Institution, the sum of 500*l.* was subscribed, and a donation of 1,000*l.* from an anonymous individual was acknowledged. It is to be hoped that a charity, so much wanted in a populous district, will no longer remain closed for the want of funds.

UNIVERSITY OF DUBLIN.

Medical Degrees.

The following regulations have been made by the University of Dublin, in imitation of those of Oxford, we presume:—

A bachelor of arts shall be entitled to examination for the degree of bachelor of medicine, on producing certificates of having attended one course of lectures, and not more than three in each of the four medical sessions, on the subjects required in Edinburgh, midwifery included. The effect of these regulations is, that more lectures are required, and the time for attending them lessened from six to four years. The degree of doctor is conferred, as in Oxford and Cambridge, without any examination! classical lore being substi-

tuted in a great measure for medical knowledge. The three universities just named possess the monopoly of conferring medical degrees without the means of teaching medicine, as well observed on a late occasion in the House of Lords by the Lord Chancellor.

**THE
London Medical & Surgical Journal**
Saturday, April 12, 1834.

GRADES OF PRACTITIONERS.—PROFESSOR GREEN.

PROFESSOR GREEN's pamphlet, of which we gave a rather full analysis a fortnight ago, has since occupied a good deal of attention, and been the subject of much criticism. On the whole, the liberality of the learned Professor has been duly appreciated, and even the organ of monopoly and conservatism has found something to admire in the various orders of architecture admitted in his scheme, for re-constructing the ruined edifice of professional education and rank. The strictures of the Medical Gazette upon the advantage of the subdivision of labour in the practice of medicine, as in every thing else of human application, are quite beside the question at issue, on which it labours to enlist the learned Professor into its service. It is notorious, that no man could live by surgery alone. It would be a curious inquiry to ascertain how many purely medical cases are daily treated by the most eminent operative surgeons in the metropolis; and among the mass of persons, practising as surgeons, it is beyond all doubt their practice is wholly medical. The present distinction between physicians and surgeons is utterly disregarded in practice by the latter; can it then admit of question, whether there should be any inquiry into the competency of every person entering into the profession to practise medicine as well as

surgery? With the parties who hold the opinions we are confuting, it were waste of time to insist upon the indivisibility of the art of healing as a scientific study. To persons properly impressed with that idea, it is as clear as noonday that no distinction ought to be allowed in the preliminary education of any member of the profession. Distinctions will nevertheless subsist as long as the demands of society call forth and reward the exercise of superior talents; and, from the unwillingness of the world to admit the superiority of any individual in a variety of branches, from the varieties of taste and natural qualifications, there will be ever found in the profession men particularly distinguished or celebrated for their knowledge of some one branch of medical science in preference to others—the Abernethies and the Baillies of the day—though the absurd distinctions of preliminary education were abolished for ever.

We have inserted, in our last number, a letter from an excellent correspondent*, which we consider particularly worthy of attention for the valuable comments it contains upon Professor Green's plan of retaining the present subdivisions of the profession, under altered names. There is, indeed, great room for doubting whether any adequate advantage would arise from the institution of a second class of medical practitioners, of a more extensive and longer education, while the first class had the right of universal practice, upon an education more limited, and occupying less time in its acquisition. It seems better to lay down at once and amalgamate the minimum and the maximum; for, however theoretically and practically correct it may be to say a certain limited knowledge is sufficient for the treatment

of certain affections, yet who can say ignorance will not be presumptuous, should opportunity of superior assistance be even at hand? And with reference to the supply of students at an increased probationary period and study, we are warranted, by what takes place in other professions not understocked, in believing there would be a sufficient supply of medical practitioners, though the whole course of the Colleges of Physicians and of Surgeons were required of every member. It would be desirable, notwithstanding, that the recognised teachers should undergo the ordeal of an express public examination for so important an office.

On one point our correspondent is in perfect accordance with Professor Green; and we estimate his invaluable testimony the more highly, because those who entertain the same opinion with him have been sometimes maliciously represented as adverse to the interests of the large class of general practitioners. Need we say we allude to the sale of medicines where the advice is gratuitous? We trust the Parliamentary Committee will examine some gentlemen like our correspondent, who are acquainted with the practical results of the system, and who have had the courage, as they saw the necessity, to separate such incompatible elements as a trade and a profession.

To counterbalance any censure Professor Green may incur by reason of his graduated scale, we extract the following excellent passage, in which a flagrant defect in medical law, as at present constituted, is pointed out, and an adequate remedy provided. We are sure our correspondent will agree with us in approving of this extract.

“Further, the Council should have the power of expelling all those from the profession who, by dishonourable practices,

* Mr. Cooke, Trinity-square.

have rendered themselves unworthy of the character of members of a liberal profession, whether it be by the use of secret remedies, by advertising, by partnerships in trading concerns, by calumnious reports of their professional brethren, breaches of professional confidence, or whatever else may be considered derogatory to a professional character*."

There are some other points on which the Professor's opinions are in complete accordance with our own; we shall hereafter dwell upon some of them; at present we shall allude to but two, on which we must reserve some comments for a future occasion,—the *parish tenders* for medical assistance and the *Dispensaries*, subjects deserving of separate chapters.

THE WESTMINSTER MEDICAL SOCIETY.

UNDER which of Polonius's classification of plays—

"Tragedy, comedy, history, pastoral, pastoral-comical, historical-pastoral, tragical-historical, tragical-comical-historical-pastoral," it may please the Polonius of the Medical Gazette to describe the proceedings at the Westminster Medical Society on last Saturday evening, our readers may amuse themselves in divining, till to-morrow reveals the secret. For our part we consider the matter which has lately so much occupied the attention of the Society, utterly unworthy of any further notice; and we earnestly hope no provocation will induce the Society to resume the disagreeable topics which, on the two last occasions, interrupted its usual business. With Dr. Gregory's private opinions, no doubt candidly adopted, upon the proper reconstruction of the medical profession,

the Society has nothing to do, however it may regret to find its general sentiments at variance with those of the gentleman elected to be its President. It is quite possible, too, that the learned Doctor may, upon further consideration, have found reason to dissent from a resolution originally penned by himself—(if we are not going too far in assuming the penmanship as undisputed). The words may have been unintentionally ambiguous. In fact, there is no reproach of necessity implied in the unfortunate estrangement of the Society from the President.—There is a difference of opinion, and that is all.

With regard to the strictures upon the conduct of one of the first Medical Societies of the kingdom by some unknown correspondent, or unknown editor, if that is to ruffle its temper, it is in the power of any discontented and malicious person to disturb its harmony, and force the recipient journal into notoriety. It must not play the game of its enemies; it must not suffer their random shafts to irritate it from the course at once becoming its dignity and its cause,—the promotion of knowledge and the respectability of the profession. We were glad to find that these sentiments generally prevailed at the last meeting, and that the proper business of the Society was resumed with much spirit after a little agitation. So much for the Medical Gazette.

Rebâtoz.

Medical Bibliography: A and B. By JAMES ATKINSON, Senior Surgeon to the York County Hospital and York Dispensary, &c. Royal Octavo, pp. 382. London, 1834. Churchill.

This is one of the most extraordinary productions we have ever perused. It abounds with sarcasm, wit, and humour. It is dedicated to "all Idle Medical Students in Great Britain."

It displays the most laborious research, as appears by the catalogue of each author's writings, together with the various editions of them in chronological order. It contains a vast deal of information, interspersed with humorous comments, such as are sufficient to cure any Esculapian hypochondriac. A specimen of the work will be sufficient to establish our decision:—

"Asclepiades was, by report, a wild erratic vagabond son of physic, but a talented man. He died and lived without physic,—I mean without taking it,—to the age of 80.—Wonderful!"

Speaking of Alexander Trallianus and Alexander Iatros, our facetious bibliographer observes:—

"But of these Alexanders I am of opinion, that Alexander the Great Physician, or Alexander the Great Conjuror, were of ten times more value to the world than Alexander the Great Conqueror."

Haller edited the whole of Alexander's works, and, after the highest eulogium on the latter, our author adds—

"There was, however, one year in the typographical life of Haller for which, for some time, I was unable to account. It was betwixt the years 1730 and 1732, wherein not any thing of typography, as I conjectured, issued from his press. But pause; for that year he was in reality employed in (tut, tut, pshaw, pshaw,) making love; preparing in sheets, and typifying by the press, a new edition of himself. In the persons of his lovely children we had, after proof impressions, all hot-pressed and perfect, ut typus typo similis."

After a reference to the works of the illustrious Haller, our humorous author alludes to a passage, and adds a comment:—

"Incerta omnibus spes est vitæ, senibus non incerta solum sed omnino vix ulla superest. Nor little can I expect to live so long as to enable me, in possibility, to proceed in my alphabet to letter H. And is not vita brevis, and tempus arctum? Are not libri multi, and nummi parci? And have I not well surveyed the mouth of that molaris fellow, old edax rerum? He is to me, reader, of frightful aspect. For teeth beset his mouth and palate in all directions—the most cruel and diversified. He is carnivorous, nay omnivorous, with most formidable trotophite muscles, which

befit him to destroy, not only poor me, but any thing."

Our readers must suppose that the author has not executed his task in the best manner; but we inform them that he has occupied eight royal octavo pages with the works of Aristotle and his editors,—all their doubts must vanish. The work reminds us of Burton's Anatomy of Melancholy: it evinces great learning, much wit, and some satire. We sincerely wish that Mr. Edax Rerum may condescend to allow the author to complete it.

An Investigation into the Medical Effects resulting from the External Application of Veratria. By ALEXANDER TURNBULL, M.D., 8vo. pp. 96. 1834. Longman and Co.

THE substance named veratria is obtained from veratrium sabadella, veratrium album, and colchicum autumnale. It is a compound of veratrine sabadelline and mono-hydrate of sabadelline. It cannot be administered internally with safety, as a quarter of a grain has produced violent purging in old subjects, such as would lead to the conclusion that a few grains would cause death. It is used externally in the form of an ointment, composed of 10 or 20 grains of the alcaloid to an ounce of lard, of which the size of a nut is rubbed on the sound skin night and morning. It is unsafe to apply it to an abraded surface, in consequence of the irritation which it would produce. It is remarkable that taken internally it excites great irritation, but used externally it allays irritation, removes pain, elevates the spirits, and improves the appetite and general health. Again, it acts as a diuretic in dropsies, but not under ordinary circumstances. Dr. Turnbull advises it in the shape of an ointment in functional disorders of the heart (his symptomatology of which is that of organic lesions), in angina pectoris, in facial neuralgia, in rheumatism and paralysis.

The experience of others must, however, determine the efficacy of this remedy. The high price demanded for it will cause it to be adulterated largely. An ounce of the ointment costs fourteen shillings, so that we would advise our readers to try cheaper medicines before they commence with veratria. The impression on our minds, after a careful pe-

result of the work before us, is, that the remedy of which it treats is rather overrated.

An Oration delivered before the Medical Society of London, at their Anniversary Meeting, March 8, 1834. By WILLIAM SHEARMAN, M.D., Senior Physician to the Charing-Cross Hospital.

This oration is well written, and reflects great credit on its author. It contains some sentiments peculiarly apposite at this time, of *Reform*, which no doubt will be placed before Mr. Warburton, as Chairman of the Parliamentary Committee. Dr. Shearman observes:

"If we advert to the state of the medical profession, at the period of the commencement of our Society, we shall perceive it to have been very materially different from that which it exhibits at the present moment. The different branches of practice were then separated by broad and distinct lines, both in public institutions, and in the private walks of life. The physician, the surgeon, and the apothecary, interfered very little, or scarcely at all with each other. The last, indeed, was qualified in some degree by the nature of his education and pursuits, to supersede the attendance of the physician, but he seldom did so, until an advanced period of his life, when a long course of practice had deservedly procured him the confidence of his patients; for it must be admitted, I think, that the genuine apothecary of the last century, occupied in the appropriate business of his own department, superintending the administration of the medicines prescribed, observing their beneficial or prejudicial effects, and watching in his frequent visits to the patient's bedside, the progress of the disease, and change of symptoms, preparatory to his periodical consultations with the physician, possessed within himself, so to speak, the elements necessary to the formation of a successful practitioner, in a far superior degree, to whatever will be found to exist in the mere pathological anatomist, however expert in his science he may be. The physician and the surgeon were totally distinct; and almost every family, even of the middle classes, had its separate physician, surgeon, and apothecary; the latter alone managed cases of illness of little importance; were the case more serious, the physician was joined with him, and only in

cases of accidental violence, or external disease, were the services of the surgeon put in requisition. In the public hospitals, at that period, a surgeon scarcely ventured farther into the walk of medicine, than to order a dose of opium, a few grains of calomel, or an ounce of salts. Every surgical patient was consigned also to the care of a physician, and the surgeon seldom knew what internal medicines were prescribed by the doctor, when his assistance in the case was demanded.

Whether such an arrangement was judicious or not, or whether it was preferable to the present confused and anomalous condition of the profession, is not now the question; the circumstance is noticed to show, that there existed not those causes of jealousy, and that constant clashing of interests, which we now witness to so great a degree, and that, therefore, the period was propitious to the cordial union of all the various branches of the profession. Causes, which have in late days exerted so baneful an influence in sowing discord among the members of our profession, and in disturbing that harmony which it is essential for the promotion of its interests and for extending the sphere of its utility should always subsist, had not then existence. No attempts had then been made to advance the prosperity of one branch on the ruins of another; each pursued its own proper course, without interruption from the rest.

"If the axiom, that the division of labour is conducive to improvement, be as applicable to science as it is to the arts, it might be expected that the exclusive attention of an individual to a distinct branch of medical science would perfect him in the knowledge of that branch, and that so the curative art, taken as a whole, would attain a degree of perfection commensurate to the labour employed. But there is so natural and inseparable a connection between medicine and surgery, that perfection can never be attained in the one to the total exclusion of the other; and experience has demonstrated, that the improvement of both has advanced at a greater rate since the preliminary education for each has been more closely assimilated: it is possible, however, to run into the opposite extreme, and by endeavouring to attain perfection in such multifarious pursuits, to fail of becoming

a proficient in any. It is most conducive to the improvement of medical science as a whole, that, after a certain course of education, one branch of practice should alone be cultivated, rather than the whole of them indiscriminately."

Clinical Observations on the Constitutional Origin of the various forms of Porrigo; commonly known by the names of Scald Head, Tinea, Ringworm, &c., with Directions for the more Scientific and Successful Management of this usually obstinate class of Diseases, &c. By GEORGE MACILWAIN, Surgeon to the Finsbury Dispensary, &c. 8vo. Pp. 83.

The author of this work is favourably known to the profession as a writer, and the volume before us shows him to be a judicious and scientific practitioner. He discusses at some length the pathology of porrigo; and argues strongly in favour of attending to the constitution in cutaneous diseases unattended by fever. Our opinions in favour of this remark are upon record, and we fully agree to his conclusion. He expatiates on Mr. Abernethy's views on the constitutional origin of local diseases, and reviews nearly all that has been written on porrigo. We find little new in the volume, in fact nothing that M. Alibert and Mr. Plumbe have not said before. The great and prominent maxim is, to improve the general health, observe the strictest cleanliness, and employ the ung. hyd. nit. diluted with seven parts of lard. The head should be shaved twice a week, and the ointment applied night and morning.

The experienced reader will find little novelty in this essay, for the recommendation of attending to the general health in cutaneous diseases is not new.

French Hospital Reports.

HÔTEL DIEU D'AIX.

(Bouches du Rhone.)

Encysted Tumours near the Outer Malleolus—Introduction of a Seton—Cure.

HENRIETTE M—, a countrywoman, ætat 27, applied for admission into the hospital under Dr. Goyrand, in consequence of two tumours, one of which was as large as a moderately sized apple, and was placed on the outer side

of the leg, rather below the external malleolus, the other being rather larger, and placed above this process of the fibula. Fluctuation was very distinct in both tumours, and on pressing them, a communication with each other, and with the sheaths of the peronei muscles was discovered. From the peculiar sensation conveyed to the hand by pressure, it was supposed that these formations were similar to the hydatid cysts mentioned by Dupuytren.

It appeared from the statement of the patient that, about five years since, she sprained the ankle of the same side; for some time afterwards there was much pain, but at length this subsided, and then she perceived two small tumours. From this period for some months, no pain was felt, but at length, as they increased in bulk, they became troublesome, and impeded her in walking.

As the woman was very desirous that an operation should be performed for her relief, Dr. Goyrand, on the 20th of July, made an oblique incision over the inferior cyst, which gave issue to a great number of small, opaque, white, isolated bodies; an incision of similar extent was made over the superior tumour, and a seton was then passed from one to the other. Violent inflammatory symptoms came on some hours after, and rendered the removal of the seton necessary, and on the following day the secretion of pus was so profuse, that the enlargement of the incision for its free exit was found necessary. On the 30th all the inflammatory symptoms had nearly disappeared, the suppuration was diminished in quantity, and the tumefaction of the surrounding parts was almost entirely gone. By the 18th of August no traces of the tumours remained; the wound was almost entirely closed; and shortly afterwards the woman left the hospital quite well. The white bodies which had escaped from the wound were of various shapes and sizes, some being ovoidal, or elongated, and as large as a grain of barley, whilst others were either angular, or spherical, and as small as a pin's head.

HÔPITAL DE LA CHARITÉ.

Paralysis of the Upper Limbs—Aphonia—Stammering cured by the internal and external use of Strychnine.

Gavel, ætat. 40, employed in a lead manufactory, has suffered for some time from

attacks of colic pictonum, of which the last was cured by the croton tiglium oil. Latterly he has complained of slight pains in the arms, pricking sensations on the soles of the feet, especially during the night; these trifling symptoms have now become much more severe; the pains being very violent, and the power over his upper limbs failing him; he is attacked also with vertigo, sudden fits of terror, watchfulness, loss of memory, and affection of the sensorium.

At his entry into the hospital on the 25th of January, the arms were completely paralysed; by great effort he was able to bring the pectoral muscles into action, and thus to direct the backs of the hands to each other; his power over these limbs extended no farther, for the muscles of the shoulder, arm, forearm, and hand were completely motionless. These limbs were in a state of atrophy, the integuments being of a yellow colour. There is no pain along the vertebral column. Blisters powdered with one-fourth of a grain of strychnine, to the palmar surface of each fore-arm, and baths of sulphur were prescribed. The latter were afterwards omitted, and one-fourth of a grain of strychnine was given internally. At the end of eight days the pains had disappeared, and there was some slight return of motion in the shoulders; the strychnine was then increased to two-thirds of a grain. After some days recourse was again had to the blisters containing strychnine. The improvement in the man's state now becomes very evident; the paralysis diminishes; the appetite is returning; and he is becoming more sensible to the smallest dose of the medicine. Towards the end of April, shower-baths of ordinary water were used in addition to the strychnine and sulphur-baths, which had again been had recourse to. On the 28th of last May he left the hospital perfectly well; at this time, his voice had quite returned, and the stammering had left him.

Tetanus—Softening of the Spinal Cord.

A young man, ætat. 18, a jeweller, admitted March 1st with tetanus. From his infancy both he and four of his brothers have been subject to convulsions. For the last four months he has often had involuntary and painful contractions of the fingers, which came on suddenly, and caused him to drop his tools.

On the 19th Feb., after slight indisposition, he was seized with stiffness in his arms, and lost his senses for a short time. A week after this he was attacked with a violent paroxysm of suffocation, and his present symptoms came on. His face is red and animated, eyes fixed, and pupils dilated; respiration loud and laborious, pulse 110, pulsations of the heart tumultuous, strong, and clear. Extremely painful cramps of the extremities, which come on in paroxysms; the fingers, hands, and forearm rigidly flexed; calves of the legs hard and contracted; thirst; deglutition easy, notwithstanding the contraction of the masseter muscles. No pain in the head, spine, or region of the heart. Bowels confined; intellect unimpaired. General and local bleeding to the spine, cold effusion, purgative injections containing musk, and opium every two hours were prescribed, from which, at first, he appeared to be relieved: the paroxysms of suffocation and tetanic symptoms returned, however, with greater violence, and he died on the sixth in a fit of suffocation.

Examination of the Body twenty-four hours after Death.—Membranes of the spinal cord very vascular: effusion of serum into the canal. In the upper part of the cord there was a spot about eight or ten lines long, and two or three broad, which was vascular, grayish, and in consistence like cream; slight effusion in the membranes of the brain and the ventricles; velum interpositum very much injected; tuber annulare and commencement of the medulla oblongata extremely firm; the pericardium contained about 3 ij. of pus mixed with serum; heart of normal size.

In this case the tetanus was evidently the result of lesion in the medulla spinalis and its envelopes. Without pretending that in all cases of tetanus, analogous lesions have been observed, there yet exists an imposing mass of cases in which it has arisen from alteration in the cord or its membranes. The observations of M. F. Pescay, Lepelletier, Mans, Carron, Ollivier, Brague, &c., are conclusive on this point.

Paralysis from Lead—Exhibition of Strychnine—Cure.

Fiault, æt. 48, has had colica pictonum six times since 1826. In January, 1833, he came under the care of M. Rayer with an attack of

colic, which was relieved by croton-oil and purgative injections, but left him affected with paralysis of the superior extremities, and complete loss of sensation in the arm and hand: the sterno-cleido-mastoides of the left side was also paralysed, and the head consequently turned to the right side. The sulphur bath was ordered daily, and blisters applied to the fore-arm, and the surface sprinkled with one quarter of a grain of strychnine. In a few days he took strychnine internally, commencing with one-eighth of a grain, and gradually increasing it to one grain. This dose was followed by violent spasms, opisthotonos, entire loss of sense, and imminent asphyxia. In two or three hours he became calm, and the internal use of the medicine was for a short time omitted, but afterwards resumed in smaller doses, and the sulphur baths continued. When he left the hospital the fingers were slightly contracted, but otherwise the paralysis was quite relieved.

HÔPITAL DES ENFANS MALADES.

Cephalalgia attended with Vomiting—Cough—Death—Alteration and unnatural Firmness of the Cerebral Substance—Tubercles in the Lungs.

A boy, æt. 12, was admitted into the hospital on the 2nd of February, for cough and paroxysms of intense pain in the head, attended with vomitings, from which he had suffered for twelve months. These symptoms persisted until the commencement of March, when he was seized with delirium and died.

Autopsy.—Head—The dura mater tense; cerebral substance pale, but unnaturally firm; convolutions flattened, and so pressed against each other, that scarcely any traces of sulci remain. *Chest*—The right lung entirely adherent to the pleura costalis; the superior lobe on this side filled with tubercles at the upper part, but in a state of ramollissement below. *Abdomen*—Tubercles in the spleen.

HÔPITAL DE LA PITIE.

Fallopian Pregnancy—Internal Hemorrhage—Death.

Guerin Elisabeth, sempstress, æt. 30, was admitted into La Pitié, in the evening of the 19th February, and died in the night. The

following symptoms were observed during the time she was in the hospital:—shiverings; pain and tension of the abdomen, excessively increased by the slightest motion or pressure; nausea; hiccup; anxiety; quick and laborious respiration; cold sweats; syncope; general pallor; restlessness; small, hard, and quick pulse; cold extremities; loss of intellect; death. Previous to her admission she had enjoyed good health; and the above symptoms had only come on three hours previously.

Examination of the Body twenty-seven hours after Death.—General paleness of the surface: no trace of any wound or violence. On opening the abdomen, at least three quarts of pure blood flowed out, and the pelvis was filled with an enormous coagulum of black blood. After having removed the blood cautiously, the hæmorrhage was found to have proceeded from the rupture of a tumour in the left fallopian tube, about an inch and half from the uterus: it was the size of a small hen's egg, of a brown-red colour, and presented in its most prominent part an irregular circular rent, about two lines in diameter. The structure of the tube at this part very much resembled placenta. At the depth of about three lines a diaphanous sac was seen, containing an almost colourless liquid, in which was distinctly seen a foetus, apparently at the sixth or seventh week. The head, trunk, and tubercles for the extremities were very visible. The uterus was double its natural size, and its walls thick, soft, and red; its cavity, increased in size, contained a dense structure, which resembled, both in texture and colour, torn pieces of placenta. This state of the uterus is described by Chaussier as constantly accompanying fallopian pregnancy. The ovaries were well developed, and natural in structure. Other organs healthy.

A somewhat analogous case was given to the Anatomical Society last year by M. Pelletier. A tumour was found adhering to the uterus, near the left fallopian tube: it was about the size of a fist, with thick and almost fibro-cartilaginous walls, and contained an adipoceros matter mixed with hair, and a portion of the upper jaw with two teeth in it. This was covered with periosteum, and adhered to the cyst by a pedicle, in which were vessels for its nutrition.

HÔPITAL SAINT LOUIS.

*Wound of the Head from a Fall—Caries;
Fistulous Opening—Application of the
Trepine.*

Alphonse Crozet, æt. 21, was thrown from his horse on the 23rd of February, 1833. He fell on the back part of his head, and was stunned by the blow, but soon recovered his senses, and was enabled to follow his occupation (that of a soldier) for two months. At the end of this time he presented himself to the surgeon of the regiment with a large tumour, situated at the superior and posterior part of the head. An incision into the wound gave exit to a large quantity of sanguineous and purulent fluid. From this time he suffered from acute pains in the head, but still continued with his regiment, until the 4th of December, when he was admitted into St. Louis. A careful examination of the part was made by M. Jobert, who stated that, although the blow had not been sufficiently violent to fracture the bone, it had caused depression of the laminae, had bruised the diploe, and had given rise to fistulous openings in the pericranium and dura mater. The state of the head imperiously demanded an operation; and accordingly, on the 4th of February, 1834, M. Jobert proceeded to trephine over the part, which was in a carious state. The diseased portions of bone were removed, and the wound was then lightly dressed.

March 2nd. The patient has not suffered from any severe symptoms since the operation; the wound has been dressed each day, and to-day (48 days after the operation) he is in the most satisfactory state, approaching rapidly to convalescence.

HÔTEL DIEU.

*Epilepsy.—Fibrous Tumours of the Dura
Mater.*

Maria Chassin, æt. 56, about a year since was seized with symptoms of epilepsy, followed by slight delirium. A fortnight ago the disease returned; the delirium continued; the limbs were contracted and rigid; there was epileptic trembling. She appeared to hear and see, but did not speak. The diagnosis was—epilepsy developed at an advanced age; inflammation of the left side of the brain, implicating the optic thalami and corpora striata;

disease of the membranes. Bleeding, cold to the head, purgatives, and blisters, were employed, but the symptoms increased, and she died Jan. 13th.

Necropsy.—The dura mater on the left side was studded, for a space the size of a five franc piece, with numerous fibrous tumours, which penetrated into the substance of the brain; they were hard, and varied in size from a hemp-seed to that of the little finger. The membranes round this part were very vascular. The cerebral substance of the left hemisphere was in a state of extreme ramollissement.

British Hospital Reports.

WESTMINSTER HOSPITAL.

Fracture of the Patella.

A STRONG athletic man, ætat. 33, was admitted with a transverse fracture of the patella, caused by the violent action of the muscles in bending his body backwards. The accident was immediately succeeded by complete inability to walk, in consequence of the extensor muscles not being able to perform their office. The separation between the two portions of the fractured bone was considerable; this, however, could with the greatest difficulty be discovered, in consequence of the great swelling which existed all over the knee. Leeches and cold applications were applied, which succeeded in bringing down the swelling. The position of the patient was as follows: he was placed on a fracture bed, his leg being extended in a gradual ascent from the tuberosity of the ischium to the foot. No straps were applied for some time after his admission. They were then used for a day or two, when they were removed in order to try the plan advised by Sir William Blizard, of applying nothing whatever to a fractured patella. The separation between the fractured portions has considerably diminished, and the case is proceeding favourably.

*Large Tumour in the Throat attached to the
Lower Jaw.*

A short time since a man came into the operating theatre in order to get advice with respect to a large tumour in his throat, which he stated to be of the greatest inconvenience to him, as it prevented him from swallowing any solid food: it also rendered his enunciation exceedingly indistinct, and almost unintelligible. It has been many years progressing, but lately it has increased in size very much. The surgeons of the hospital examined the patient's throat, introducing the fingers into the fauces with the view of ascertaining the size, attachments, &c. of the tumour. It was discovered to be of considerable dimen-

sions, and attached to the lower jaw. All the surgeons, with the exception of Mr. Guthrie, declined operating, on the grounds that the parts which would necessarily be involved in an operation were so important as to render such a procedure very precarious and dangerous; also that the patient might live many years with the use of a tube, by which he might swallow his food. Mr. Guthrie said that he did not think the patient would live long if an operation were not performed; he would most willingly undertake the operation if any other surgeon would say he was justified in so doing; and as to the importance of the parts, if the carotid artery was in the way it could be easily tied. The case was postponed for further consideration.

BOOKS.

THE Monthly Archives of the Medical Sciences, April, 1834. Edited by DR. HUNTER LANE. London: Churchill.

Outlines of the Anatomy and Physiology of the Teeth, &c.; their Diseases and Treatment: with Practical Observations on Artificial Teeth. By DAVID W. JOHNSON, M.R.C.S. Dentist in Ordinary to his Majesty. 8vo. pp. 270, plates. Edinburgh, 1834. Tait.

A concise yet comprehensive manual of dental surgery.

On the Motions of the Earth and Heavenly Bodies, as explainable by Electro-Magnetic Attraction and Repulsion; and on the Conception, Growth, and Decay of Man, and the Cause and Treatment of his Diseases as referable to Galvanic Action. By P. CUNNINGHAM, Surgeon, R.N. 12mo. London, 1834. Cochran and M'Crone.

This work will be perused with pleasure by the general and medical reader.

Letter to Henry Warburton, Esq., Chairman of a Committee of the House of Commons, appointed to Inquire into the State of the Medical Profession. Edinburgh, 1834.

CORRESPONDENTS.

SEVERAL unpaid letters have been refused.

Dr. Hake will hear from us.

Mr. Atkinson.—It is under notice.

Medicus.—It is a breach of privilege to publish the evidence before the Parliamentary Committee.

A Student.—The complaint is frivolous.

Censor.—It can not be possible that a hospital surgeon charged 100*l.* for six weeks' attendance on a case of white swelling of the knee-joint, and afterwards sent in a bill for splints to the amount of 6*s.* 8*d.* The thing is impossible—we don't believe it.

A Surgeon.—The names of quacks are in the list of the College of Surgeons. This is supporting the dignity of the profession, we suppose.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXXV., DELIVERED APRIL 10, 1833.

GENTLEMEN,—I now proceed to consider *diseases of the eye itself*; and first, *inflammation of it*, termed *ophthalmia*, the most frequent of all its disorders, and that, indeed, which may likewise be connected with any other complaint of the eye, either as a cause or an effect.

I may say, gentlemen, that it is only of late years that the various inflammatory affections of the eye have been well discriminated; for *ophthalmia* used to be a term applied to every inflammation of the eye, or parts appertaining to it, whether the eyelids, the conjunctiva, the sclerotica, the iris, or the retina, were the structure chiefly concerned; and although the epithets *mild* and *severe*, *dry* and *humid*, *external* and *internal* were frequently used, the more valuable distinctions, deducible from the structure principally affected in different examples, the characteristic symptoms of each variety, and its most appropriate treatment, were altogether overlooked. In whatever parts inflammation occurs, you know, gentlemen, that its effects are always modified by the structure affected. Now the eye, small as it is, contains a great variety of textures, each possessing both physical and vital properties peculiar to itself, and consequently exhibiting, under the process of inflammation, phenomena which are peculiar to it.

I may say, gentlemen, that modifications of inflammation, arising from differences of texture in the parts affected, are often beautifully displayed in the eye, and this in so distinct a manner, that its appearances and changes under inflammation are commonly cited by all pathologists of every school, in illustration of various points relative to the nature of this interesting process.

VOL. V.

One thing which I conceive it is very useful to understand is, that inflammation of the eye generally commences in one structure, to which it is at first restricted, and beyond which, if it be rightly treated, it may not materially extend. But, gentlemen, if it be neglected, or wrongly treated, it soon exceeds its original limits, and perhaps ultimately invades every part of the organ. The conjunctiva, the sclerotica, the cornea, the iris, the crystalline capsule, and the retina, all severally exhibit a series of the modifications of inflammation, dependent upon peculiarity of texture. The mucous tissue of the conjunctiva secreting a profuse quantity of purulent matter, as in the *ophthalmia* of new-born infants; the *fibrous sclerotica*, affected for months with rheumatic inflammation; the *transparent fibro-cartilaginous cornea*, becoming opaque, or being destroyed, layer after layer, by ulceration; the *erectile iris* losing all power of executing its motions of expansion and contraction; the *crystalline capsule* pouring out coagulable lymph from its serous surface, and this lymph forming the medium of morbid adhesions; the *nervous retina*, too deeply seated to be immediately observed, but, in a few hours, losing its inconceivably delicate and specific sensibility, which is adapted only to vision, and not to common feeling, as the researches of Sir Charles Bell make evident, are all so many circumstances illustrating the modifications of inflammatory action, and the various consequences of it in different textures of the eye.

Gentlemen, you will likewise find, that inflammations of the eye, besides being modified by differences of texture, are much influenced by peculiarities of constitution, constitutional diseases, and certain artificial states of the constitution; and they are subject to innumerable variations from the influence of those inscrutable connexions called sympathies. Scrofula, syphilis, gout, disorder of the digestive organs, and that deranged state of the system which is sometimes termed *mercurialism*, are each of them either capable of exciting inflammation in different parts of the eye, or, at least, of communicating to an inflammation, excited by other causes, such differences in character as shall often render the

A A

recognition of a disease difficult, though we may be perfectly familiar with it in its more simple form.

With respect to the treatment of inflammation of the eye in general, I may observe to you that, if the disorder be not speedily checked by efficient and active means, it will soon extend from the texture originally attacked to others, and that its continuance beyond a certain period will permanently impair the delicate structures of the organ, or even cause total annihilation of its functions.

Hence, gentlemen, the necessity of adopting very active treatment, and this, not on account of any danger to life, or any extraordinary suffering, great as this may be, but to prevent those changes of structure which would weaken or destroy the eyesight. Hence you are frequently called upon to take away as much blood from the system for an inflammation of the eye, as for an inflammation of the pleura, or lung, stomach, or brain, or any other important internal organ.

If prompt and vigorous treatment be not adopted in the early stage of inflammatory affections of the eye, you will frequently find lymph effused, or opaque matter deposited in the transparent parts of the eye; or the retina will be more or less impaired in texture and sensibility, the pupil be rendered irregular, the motions of the iris prevented by adhesions; or the complaint will degenerate into a chronic form, sometimes difficult of cure, and always lessening the chance of such a recovery as leaves behind it no defect or weakness whatsoever of the eye, either with reference to its movable, its transparent, or its nervous textures.

External inflammation of the eye may be seated in the conjunctiva only, or in the sclerotic and cornea. Simple inflammation of the conjunctiva, you will generally find, is a much less serious complaint than that of the sclerotic. Yet, specific inflammations of the conjunctiva are exceedingly urgent cases, as, for instance, violent purulent and gonorrhœal ophthalmies, which, if unsuccessfully treated, soon involve the organ in incurable mischief. In sclerotic inflammation, however, the implication of the cornea, and the ready transition of the inflammation to the iris, always expose the organ to considerable danger.

From these preliminary remarks, I proceed to the consideration of the chief varieties of ophthalmia, beginning with *Inflammation of the Conjunctiva*, divided into the following kinds:—

1. Simple or catarrhal.
2. Purulent contagious, or Egyptian.
3. Leucorrhœal, or the ophthalmia of new-born infants.
4. Gonorrhœal.
5. Scrofulous.

1. *Simple Inflammation of the Conjunctiva*.—*Catarrhal Ophthalmia*, as it is often called, generally commences with stiffness and smarting of the eyelids, or a sensation, as if

sand had got under them, an increased secretion from the lachrymal glands, giving a watery appearance to the eye, with some degree of redness and uneasiness upon exposure of the organ to the light. When fully developed, the disease is characterised by considerable redness, and the increased lachrymal discharge is exchanged for one of a thin, whitish mucus, but the pain is generally slight, and now there is no intolerance of light. The redness is superficial, and the tint, a bright scarlet, forming a striking contrast to the rose or pink colour which belongs to inflammation seated in the sclerotic. The distended vessels form a network, and the redness is in patches; though in the fullest development of the affection, the whole surface of the conjunctiva becomes of a bright red; the redness first showing itself at the circumference of the eyeball, and gradually advancing towards the cornea. In severe cases, small ecchymoses, or effusions of blood, may be noticed in the conjunctiva; and sometimes little vesicles, filled with a serous fluid, arise upon it, near the margin of the cornea.

Gentlemen, the conjunctiva is seldom considerably swollen, and never in the degree exemplified in what is termed *chemosis*, or that remarkable elevation of the conjunctiva which is sometimes caused in other ophthalmies by effusion of lymph underneath it. There is, however, a certain quantity of serum poured out under it, whereby it is somewhat raised up from the sclerotic.

As soon as the lachrymal discharge, observed in the very commencement, stops, its place is supplied by an increased secretion of mucus, which is at first thin, but becomes thicker, as the inflamed conjunctiva goes through certain stages, assuming a whitish or yellowish appearance, and even that of pus. It is this altered secretion, which drying on the eyelashes in the night-time, makes the eyelids adhere together, so that the patient has a difficulty in opening them in the morning.

In every well-marked case of catarrhal ophthalmia, the eyelids participate in the affection; and whenever the attack is severe, other mucous membranes suffer. Hence pain and sense of weight about the frontal sinuses and antrum, disordered stomach, foul tongue, chills, succeeded by heat, and other febrile complaints.

Simple inflammation of the conjunctiva is distinguished from common inflammation of the external tunics by its catarrhal origin; the diurnal remission and nocturnal exacerbation of the symptoms; the absence of pain and of intolerance of light, even when there is great general redness; the bright scarlet colour of the membrane, the distended state, and areolar arrangement of its vessels, and the altered mucous secretion from the lining of the eyelids. From purulent ophthalmia, it is distinguished by its milder nature; its indisposition to do mischief to the cornea or the deeper textures of the eye; its not being in-

fections or contagious; its having no tendency to cause chemosis; and its freedom from all the severe sufferings which attend bad forms of purulent ophthalmia.

The origin of this complaint is generally ascribed to atmospheric causes—exposure to drafts of air or cold winds—sudden changes from heat to cold. Frequently it prevails as an epidemic in certain towns and districts, owing to particular states of the air, not precisely ascertained. We know that an ophthalmia of this kind prevailed at Newbury to a great extent about fifty years ago, and that it sometimes shows itself extensively in schools. For its relief mild antiphlogistic treatment will generally suffice; and it is not necessary to reduce the patient so much as in some other inflammatory affections of the eye. Unless the patient be of a full habit, or both eyes be severely attacked, you need not therefore always have recourse to venesection. In ordinary cases, cupping and leeches will answer the purpose. The bowels, however, should be freely opened; and if the tongue be foul, an emetic ought to follow the loss of blood. Saline and sudorific medicines, as a solution of the sulphate of magnesia, with a proportion of tartarised antimony in it, may then be given repeatedly, and the feet put into warm water at night. In a case of severity you might, after depletion, put your patient, in the evening, into the warm bath, and directly he is taken out of it, give him a full dose of the pulv. ipecac. comp.

As local applications, you may first bathe the eye with the decoction of poppy-heads, or foment it; but afterwards, when the inflammation is on the wane, do not be afraid of using astringent lotions, containing three or four grains of the nitrate of silver or sulphate of copper, in \mathfrak{z} iv. of distilled water. These, with blisters on the nape of the neck, or behind the ear, will generally soon complete the cure; if not, the remains of the disorder may be got rid of by introducing into the eye once a-day a drop of the vinum opii, or of the liq. plumbi acetatis. To prevent the agglutination of the eyelids in the night, their edges may be smeared at bedtime with spermaceti ointment.

2. *The Egyptian ophthalmia*, reputed to be contagious, is one of the most violent forms of purulent ophthalmia. We had no correct description of it until after the return of the British forces from Egypt, about thirty-three years ago, when it was supposed they either brought the disease to this country, or, at all events, made it more common than it had been previously to that epoch. The first stage, that in which no pus is secreted, never surpasses thirty-six hours, and is often of shorter duration. At the end of this time, purulent matter is always formed on some portion of the conjunctiva. Frequently the patient makes no complaint till he finds that his eyelids adhere together in the morning, or till the sensation of some extraneous substance in the eye becomes distressing. In some cases, a sudden

attack of darting pain in the eyeball or forehead, is the first thing experienced; while, on other occasions, the increased vascularity of the conjunctiva first excites notice.

The right eye is more frequently attacked than the left. It is also in general more severely affected, and the sight of it more frequently lost. In some instances only one eye suffers, but more commonly both, although there is often an interval of several days before the second becomes inflamed. A considerable itching is first felt in the evening, or a sensation as if there were dust in the eye, which becomes watery. This is succeeded by a sticking together and stiffness of the eyelids in the morning, which parts appear more swelled than natural. Their internal surface is inflamed, tumid, and highly vascular; and the caruncula lachrymalis enlarged and reddened.

Generally in about twenty-four or thirty-six hours, the discharge from each eyelid is already considerable. It is at first thin, but soon becomes viscid and opaque, and lodges particularly about the internal angle. There is also a frequent gush of tears, an *epiphora*, especially when the eye is exposed to a current of air. The patient complains of a sensation as if the eye were full of sand, but seems to experience, comparatively speaking, little uneasiness from the light. In the second stage, the discharge becomes truly purulent, and, in many cases, so abundant, that, on the patient opening his eyes, the matter instantly flows over the cheek, irritating and excoriating it. The quantity of the discharge sometimes amounts to several ounces in the day.

The whole texture of the conjunctiva may be seen to be swollen and thickened; its vascularity is increased; and its colour an intensely bright red. Its mucous surface is rendered villous, pulpy, and granular, like the villous surface of the foetal stomach, and from the secreting surface thus produced, the puriform discharge flows.

When not checked by effectual treatment, this species of ophthalmia soon attacks the layer of the conjunctiva, extended over the cornea, thickening it, and rendering it more or less opaque. By these changes, vision is much diminished, and very frequently the opacity and consequent diminution of vision continue after all the acute symptoms have ceased. But, gentlemen, the change in the cornea is not confined to this affection of the delicate layer of the conjunctiva covering its surface; there is often an interstitial deposition between its layers, producing a still worse kind of opacity; and frequently its texture sloughs or ulcerates; the anterior chamber being opened, and a discharge of the humours, and a prolapsus of the iris, being the too frequent consequences. In this manner both the function and form of the eye may be destroyed.

In some cases, the inflammatory process is still more severe, extending even to the internal textures of the eye, accompanied by a deep throbbing pain in the eye, coming on in

paroxysms; but occasionally without any remission in its violence till the cornea gives way.

The duration of the paroxysms of pain, and their recurrence, are quite irregular. They come on, however, most frequently from ten to twelve at night, with an increased secretion from the lachrymal gland, and a diminution of purulent discharge.

Sometimes the swelling of the conjunctiva is such, that the upper eyelid cannot be raised, and projects so enormously, that the lower eyelid is entirely concealed by it, attended with a great deal of redness of the integuments, extending even to the cheeks and forehead.

In many instances, the conjunctiva forms a prominent red swelling all round the cornea, so as to give the appearance of a thick ridge of flesh encircling the latter membrane, which seems as if it were sunk in the eye, with only a very small portion of its centre discernible. This state is technically named *chemosis*. If the purulent matter be allowed to be some time upon the cornea, it may acquire a thick consistence, and so resemble sloughy membrane that an inexperienced surgeon may suppose the cornea has been destroyed.

Whether the infection can be propagated from one person to another, through miasmata in the air, arising from the diseased eye, is a contested point; but that it can be transmitted by direct application of the discharge from a diseased to a sound eye, is tolerably certain. In the military asylum, and some other public establishments, the matter of purulent ophthalmia has occasionally been applied inadvertently to the eye of another person, and the disease been excited. Yet it is curious, that the surgeons of the French army in Egypt never suspected its contagious nature.

In Egypt, and some other countries, in which it prevails to a great extent, the origin of it is usually ascribed to the combined effect of exposure of the eye to vivid light and heat reflected in the day-time from a sandy soil, followed by exposure of the organ to the damp, cold, nocturnal air.

The constitutional symptoms are, generally speaking, influenced by the degree of pain and inflammation, a frequent but soft pulse, not much heat of the skin, the tongue white, not much thirst, the appetite good, the bowels torpid. On the whole, the constitution suffers less than might be expected.

Gentlemen, the following are some of its differences from catarrhal ophthalmia:—1st. The peculiar change of structure in the lining of the eyelids; 2nd. The frequently long continuance of the complaint; 3rd. The disposition to relapses; 4th. The tendency to chemosis; 5th. The greater swelling of the eyelids; 6th. The great increased vascularity and redness of the conjunctiva, and the copious purulent discharge.

The treatment is strictly antiphlogistic, beginning with bleeding, which, in young, strong persons, may be carried at once to the extent

of thirty or forty ounces. This is absolutely necessary if *chemosis* already exist; leeches should also be applied about two hours after venesection, which is to be repeated according to circumstances, the renewal of inflammatory action, and the state of the pulse. As long as there is a throbbing pain in the eyeball and orbit, the repetition of bleeding is generally proper.

Purgatives are to be given, as a dose of jalap and calomel, followed by a solution of sulphate of magnesia, containing in each dose one-fourth of a grain of tartrate of antimony.

When severe nocturnal pain is experienced in the orbit, much benefit has resulted from giving every night two grains of calomel and one of opium until the mouth is sore; but, under other circumstances, and I might say under every condition, the free use of mercury is of no service in purulent ophthalmia.

In the chronic stage, when the patient is much debilitated, and the discharge profuse, bark and other tonics are sometimes prescribed. When the cornea is threatened with sloughing, the same medicine is occasionally given. The local treatment seems to me to be fully as important as the constitutional.

The first point is completely and frequently, in the course of the twenty-four hours, to clean away the puriform discharge from the eyes. This is to be done partly with a bit of sponge, and partly with a small syringe, and a tepid solution of one grain of the oxymuriate of mercury in eight ounces of distilled water.

The best astringent application for checking the secretion is now generally allowed to be a solution of the nitrate of silver—four or six grains to an ounce of distilled water, and applied once, or at most twice, in the twenty-four hours. Dr. Ridgway, an army surgeon, even ventured upon twelve grains to an ounce of water, and has published a report in favour of this strength; while Mr. Guthrie gives the preference to an ointment containing ten grains of it to 3j of lard. Its use is to be preceded by washing away the discharge with a weak solution of oxymuriate of mercury, or of alum 3ss to half a pint. In the early stage, relief will also be derived from anodyne fomentations, Dover's powder at night, and a mild ointment to prevent adhesion of the eyelids.

Purulent ophthalmia of new-born infants is often believed to arise from the eyes coming in contact with leucorrhœal discharge in the birth. In a great proportion of cases, the mother has vaginal discharge; exceptions are met with, however, and then the influences of drafts of cold air, or of exposure of the young eye to vivid light usually fall under suspicion.

In general, the eyelids are first remarked to be glued together about the third day after birth, but sometimes much later. On opening them a drop of thick white matter is discharged, and their inner surface is found to be swollen and vascular. If the disease be not checked, the swelling of the conjunctiva rapidly increases, and the inflammation extends from

the conjunctiva of the eyelids to that of the eyeball. The purulent discharge becomes copious, and the skin of the eyelids assumes a dark red colour. Light is now exceedingly painful, the child turns its head from it, and resists every attempt to open the eye.

In this state the eyes may continue about a week, without any affection of their transparent parts, except a slight haziness of the cornea. About the twelfth day, however, suppuration generally takes place between the layers of the cornea, its texture becomes destroyed, it ulcerates, the humours are discharged, and the iris protrudes.

If the disease be seen before the cornea has suffered, the prognosis is favourable. If the cornea has sloughed or ulcerated, the loss of sight is inevitable.

In the third stage there is a gradual abatement of all the symptoms; the redness, swelling, and discharge are diminished; the light can be endured, and the eye is more easily examined.

Treatment.—One or two leeches may be put on the swollen upper eyelid. The bleeding from the bites will often reduce an infant very seriously, and perhaps, in ordinary cases, it is best to be content with a single leech; the discharge to be washed away with a tepid solution of alum, or oxymuriate of mercury. The lids are to be gently opened, and the discharge removed with a small bit of sponge. The upper lid has a tendency to remain everted, but it may usually be replaced, if the swollen conjunctiva be first pushed back with a probe into its right situation. For checking the discharge, use a solution of the sulphate of copper, or nitrate of silver, four grains of the latter or six grains of the former to an ounce of water, and let it be applied once or twice a-day with a large camel hair brush to the whole surface of the inflamed conjunctiva.

Then, gentlemen, you will not forget to apply the ung. cetacei to keep the eyelids from sticking together in the night. If there be a tendency to chemosis, one or two leeches are never to be omitted; the bowels are to be opened with castor oil; and a blister put on behind the ear. In tedious cases I usually give small doses of calomel. The vinum opii is one of the best things for removing the relaxation of the conjunctiva, left after the cessation of the discharge. Sometimes the disease has been successfully attacked with the nitrate of silver ointment, ten grains to one ounce of lard. The granular state of the conjunctiva generally yields to astringents, and the nitrate of silver, or sulphate of copper.

Gonorrhœal ophthalmia in its acute forms is a violent inflammation of the mucous membrane of the eyeball and lids, attended with profuse discharge of matter, closely resembling in all its sensible properties, that which issues from the inflamed urethra in clap, and occurring in some kind of connexion with the latter complaint.

It is the most severe and rapidly destructive inflammation to which the eye is subject, but fortunately one of the most rare. It is not the

consequence of the sudden suppression of gonorrhœa, for, in a great majority of examples, the gonorrhœal discharge is not stopped, though, when the affection of the eyes begins, the clap may be on the decline. As gonorrhœa is so common, and this species of ophthalmia so rare, doubts have often been raised about its connexion with gonorrhœa at all. Indeed the mode of infection has not often been unequivocally traced, but that the discharge from the urethra of one individual applied to the eye of another person will bring on the disease, seems well proved by facts collected by Mr. Lawrence, and even that the matter of clap, applied to the patient's own eye, will bring on this destructive ophthalmia, is exemplified in the consequence of the vulgar custom of attempting to cure sore eyes by washing them with the patient's own urine; for, if he happen to have gonorrhœa on him, the matter is then applied directly to the eye, and a destructive purulent ophthalmia is the result, as shown in Mr. Lawrence's work on the Venereal Diseases of the Eye. The symptoms are those of purulent ophthalmia in the severest form, intense redness, extensive swelling, chemosis, and profuse discharge of thick yellow fluid, quickly followed by ulceration, sloughing, or opacity of cornea.

Treatment is not essentially different from that of other severe purulent ophthalmies. The bold-est antiphlogistic measures, copious venesection, cupping on the temples, numerous leeches, &c., followed by blisters, warm or cold collyria, according to the patient's feelings, the same as for other purulent cases.

A strong solution of nitrate of silver, ten grains to an ounce, or the strong ointment of the same, has been employed.

When the cornea sloughs and the patient is reduced, you may prescribe bark. It is alleged that, in gonorrhœal ophthalmia, the structure of the palpebral conjunctiva is not changed, does not become granular, and that one eye is often affected, and that the disease may begin on the sclerotic conjunctiva. These points are all different from those usually noticed in ordinary purulent ophthalmia of adults.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XVII.

Aneurism of the Hepatic Artery—Distention of the Liver, with Bile—Treatment of Acute Hepatitis—Employment of Mercury—Symptoms of Suppuration—Rarity of Adhesions—Dr. Graves's Operation—Rupture into the Peritonæum—Chronic Hepatitis—Complication with Disease of the Heart—Embryonary state of the Liver—Mistaken for Chronic Hepatitis.

GENTLEMEN,—You may remember, in one of

my past lectures, I alluded to a case of aneurism of the hepatic artery, of which I had procured a preparation: to-day I shall be able to exhibit to you the morbid appearances in this very remarkable case. It would appear that aneurism of the hepatic artery is an exceedingly rare circumstance. At a late meeting of the Academy of Medicine in Paris, a specimen of aneurism of the hepatic artery was presented to the Society; and that celebrated pathologist, Cruveilhier, stated, that it was the first of the kind he had ever seen. I wish to bring this preparation before you, not merely from the interest which its rarity excites, but also because the disease, in this instance, produced that distended condition of the gall-bladder to which I drew your attention on a former occasion, and which, in this case, was recognised before death. The gall-bladder formed a distinct pyriform tumour, situated a little above the iliac fossa, and the patient was deeply jaundiced. I shall state, from recollection, what I know of the details of this case. The patient was brought into the Meath Hospital labouring under jaundice, which he stated to be of some days' standing. He was thin and weak, and when questioned respecting his age, he said he was thirty-five, but he appeared to be upwards of fifty. His habits he described as being uniformly temperate and regular. Some years before he had suffered from an attack of apoplexy, but after this had enjoyed good health, until the occurrence of the present illness, which began with vomiting of blood, and which continued for some days and then yielded to medical treatment. He now experienced a loss of appetite, became quite dyspeptic and constipated; he also began to lose flesh, and under these circumstances applied at a dispensary, where he got various remedies without any benefit. Some time after this, he observed, on getting up one morning, that his arms and legs looked rather yellow; on the following day he had a decidedly bilious tinge with yellow vision, and in this state he entered the Meath Hospital. On admission he presented symptoms of general jaundice; the urinary secretion was deeply coloured; the skin, eyes, and nails yellow; the stools white and without any trace of bile. On examining the abdomen, the liver was apparently greatly increased in size; in the epigastric region there was a tumour of considerable dimensions; and in the iliac fossa we observed a separate pyriform tumour, which could be traced up to the edge of the enlarged liver. I mentioned, at that time, to the class, that there was something about the case which I could not understand. The disease was of inconsiderable standing; the patient had, a short time previously, been in a state of good health, and yet, reasoning from analogy, this hepatic tumour could only have occurred as the result of chronic disease. It must have been the consequence of disease more or less chronic, and yet the history of the case was at variance with the idea of its chronicity. After some time the patient got milia-ry eruption,

then petechial spots; he continued in a low and weak state, and nothing did him any good. On the morning of the day of his death he did not appear worse than usual; he answered our inquiries respecting his health in his ordinary manner; in the evening he sat up in bed gasping for breath, with a look of extreme distress; he then leant back on his pillow and expired.

On opening the peritonæum we found a vast quantity of blood effused into its cavity, and my first impression was, that it was aneurism of the abdominal aorta. On closer inspection, the aorta proved healthy, and the aneurismal tumour was found to be connected with the hepatic artery; this had ruptured close to the gall-bladder, and its contents had been effused into the cavity of the peritonæum. We now found that the cause of the jaundice had been the pressure which this tumour had exercised on the biliary ducts. In consequence of the obstruction to the flow of bile, the ducts of the liver were dilated to an enormous extent; some of them were capable of admitting the largest sized finger. This dilatation affected not only the larger trunks, but even extended to their most minute ramifications, even up to the surface of the liver; and here we found that the biliary tubes were dilated into sacs, some of which were as large as a hazel-nut. When these pouches were punctured the bile gushed out freely. A similar condition of the ducts has been noticed by Mr. Lloyd as existing in connexion with obstruction of the biliary duct, from disease of the head of the pancreas, in his paper on Discharge of Fatty Matter from the Bowels. (See *Med. Chirurg. Trans.*) I have got the preparation of this singular disease before me, and I regret that in one respect it is defective, inasmuch as it does not show satisfactorily the condition of the biliary ducts. A portion of the preparation which exhibits this appearance I gave to Dr. Houston, the Curator of the Museum at the College of Surgeons, and I am sure that he will give admission to any gentleman who is anxious to examine it. This preparation, gentlemen, is too large to send round. It exhibits the hepatic artery with its aneurismal tumour, and the opening by which the artery communicates with the aneurismal sac. Here is the place in which the rupture took place, and here is the gall-bladder greatly distended and thickened in its coats.

Here, then, we have a new cause of jaundice, where the disease is the result of the pressure of an aneurismal tumour of the hepatic artery,—a cause which has hitherto been unnoticed by writers on jaundice. The great interest of this case consists in this, that dissection explained the difficulty which I felt in making the diagnosis at first, for it showed that the hepatic tumour was formed, not by an hypertrophied, but by a distended and displaced liver. It proved that it was formed, not by a process of chronic growth, but by the rapid formation of an aneurismal swelling and the consequent obstruction of the gall-bladder,

accompanied by distention of the liver itself. With recent symptoms, then, we had, in this case, *an enormously large liver, not the product of acute inflammation, but of distention of all the biliary ducts up to their most minute ramifications, and arising from mechanical obstruction.* As far as it goes, this case appears to me to be perfectly unique.

Let us turn now to the treatment of acute hepatitis. It is unnecessary for me to say, that in all cases of acute visceral inflammation in the healthy subject, the first consideration is blood-letting, either general or local. In the early period of acute hepatitis, all authors have agreed in strongly recommending the use of the lancet; and there can be no doubt that when the disease is in its early stage, and the patient robust, the practitioner who omits employing these measures, must be culpably negligent. It should always be borne in mind, that the liver is an organ of paramount importance to life. There are two circumstances, also, which are in favour of bleeding in the case of an acute hepatitis—there is less chance of its being complicated with typhus fever, and general bleeding exercises a powerful influence over the acute inflammations of parenchymatous organs. Hence we bleed with greater advantage in a case of acute hepatitis than in the inflammations of mucous membranes. Our first bleeding should be large, and such as will make a decided impression, and it will frequently be necessary to bleed a second and even a third time if the disease be very acute and the constitution strong, taking care to diminish the quantity at each successive bleeding, and to watch its effects. I have here to make one remark,—that general bleeding is not the same heroic remedy, nor has it the same decided influence in arresting acute hepatic inflammation, as in checking pneumonia. A copious detraction of blood has, under favourable circumstances, often succeeded in completely removing an attack of pneumonia, and the patient has recovered without the employment of any other remedial measure; but acute hepatitis is seldom or never cut short in this way. Still venesection is of the greatest importance; and if it were performed merely with the view of preparing the patient for leeching and other depletive measures, its advantages would be unquestionable. I would recommend you, therefore, when you meet with a case of hepatitis in the early period, first to bleed freely, or in such a manner as to make a decided impression on the symptoms; next, to empty the bowels by prescribing a purgative draught, assisted by an enema; and, lastly, to cover the region of the liver with leeches. You will find great advantage in employing your therapeutic means in this order; for if you begin with leeches before you have had recourse to venesection, or the use of purgatives, your practice will not be so scientific, nor will your success be so complete. Bleeding, purgation, leeches, and the application of cupping glasses over the leech-

bites (if necessary) will give you breathing time; and, after the lapse of twelve or fourteen hours, you will find that all symptoms of urgent danger will have passed away. During the progress of the case, the remedy which I should principally rely upon is local bleeding, frequently repeated. If you apply thirty leeches to-day, I would not have you repeat them to the same amount to-morrow; but you might, perhaps, apply fifteen or eighteen, and the next day ten or twelve. By proceeding in this way, you will find a great abatement in your patient's symptoms; and I know of no circumstance which, taken singly, proves the value and benefit of your treatment so well as the diminution of the hepatic tumour, which you can accurately and satisfactorily ascertain by means of the pleximeter. When you find a gradual subsidence of swelling, I think you may be pretty sure that, even though the other symptoms exhibit little or no improvement, the hepatitis is on the decline, and will soon be removed entirely.

You have all, I am convinced, heard a great deal of the use of mercury in hepatitis; and there appears to be in the minds of most medical men a strong connexion between mercury and all diseases of the liver. So far has this impression gone abroad, that to some practitioners it would appear perfectly heterodoxical to think of attempting to cure an hepatic inflammation without this accredited panacea. I must, however, confess, that it is my belief that several cases of hepatic inflammation may be cured without it; and, if this be true, as I am convinced you will find by experience, it is so much the better for the patient. I do not mean to depreciate the value of this powerful remedy in making this assertion;—it is undoubtedly a useful adjuvant, but it is only an adjuvant. It is decidedly secondary and inferior to general and local antiphlogistics, followed by counter-irritation; and you should always bear in mind, that if you wish to bring about the full action of mercury on the system, you must precede its employment by means calculated to reduce the intensity of local inflammation. By premising general bleeding, leeching, and purgatives, you give the mercury an opportunity of exerting a decided influence on the salivary glands; and in such cases it is, that the most unequivocal advantage is derived from it; for, as I have observed in a former lecture, salivation appears often to be the *result* of the reduction of inflammation to a certain degree, and not its cause.

In all cases of hepatitis occurring in delicate females, but particularly in persons of low, scrofulous constitutions, endeavour to dispense with the use of mercury if possible. You will have considerable difficulty in divesting yourselves of early prejudices, and combating those of others; but when you have an opportunity of acting for yourselves, I would have you make trial, and you will find that many cases are curable without mercury. If, after having regularly and carefully employed the

means recommended, you perceive that two or three days pass without any improvement in your patient's symptoms, and that the hepatic tumour remains undiminished, then indeed you may have recourse to mercury. But if you have been so fortunate as to have struck a decided blow in the commencement, and that the case is going on well, I would ask, why should you expose your patient to the misery and danger of salivation? I am not by any means opposed to the employment of mercury in cases of liver disease; on the contrary, if we compare inflammation of the lungs, brain, and liver, with respect to the power which it has over each, I believe that it is much more applicable to cases of hepatic inflammation than it is to either pneumonia or cerebritis.

There is nothing more common than a complication of disease of the liver with disease of the upper part of the digestive tube; and here you will find that calomel will frequently cause great irritation of the bowels, vomiting, and increase of fever. Under such circumstances, you must omit the internal use of mercury, and have recourse to frictions, directing your patient to rub in a drachm of camphorated mercurial ointment every six or eight hours until the gums are affected. A very good auxiliary means is to place a drachm of the mercurial ointment in the patient's axilla, and leave it there; the action of the arm will, to a certain extent, answer all the purposes of friction. Dr. Graves is much attached to this mode. Where you have employed blisters, you may cut off the cuticle, and dress the raw surface with mercurial ointment. This also will contribute materially to produce the intended effect on the system. With respect to blisters, the same rules are to regulate their application as I have mentioned before, when speaking of the treatment of gastro-enteritis, namely,—that they are not to be used until active antiphlogistic treatment has been employed; for it is then, and then only, that the stimulus of a blister can be useful. I believe it is seldom necessary, or even safe, to apply a blister before the third or fourth day in cases of acute inflammation of the liver. The physician who purges to-day, and blisters to-morrow, and bleeds the next day, is a very injudicious practitioner indeed; he should bleed first, then purge; and, having by these means reduced the symptoms of active inflammation, he may proceed to the use of blisters with advantage.

It is unnecessary for me to remind you, that you must enjoin a strict antiphlogistic diet in all cases of acute hepatitis. Recollect the powerful influence which all dietetic stimulants exercise, not only over the digestive canal and general system, but also over the liver; bearing this in mind, you will, for the first few days, keep your patient on a water and slop diet, and then on mild farinaceous food and chicken-broth.

But suppose that after all this, after having

employed all the resources of the science and art of medicine, your patient becomes gradually weaker, his face pale and expressive of much constitutional suffering, his skin flaccid and bedewed with perspiration, his pulse small, rapid, and compressible; that the hepatic tumour increases in size, and when you throw aside his bedclothes, the whole of the right side appears manifestly enlarged; and, if the bowels are empty, you see the hepatic tumour extending far downwards into the abdomen: in addition to these symptoms, suppose the patient has had shivering fits, not only once but repeatedly; that his perspirations are profuse, and have a sour smell; that his tongue is dry and glazed; that his cheeks are hollow, and sometimes present a circumscribed flush; and that he is low, weak, and restless. Under these circumstances, you may be sure that suppuration is commencing, or has been already established; and the question is,—what are you to do? You must change your hand, you must give up antiphlogistics, you must omit the employment of all measures which have a tendency to reduce strength, you must prescribe a light nutritious diet, and anodynes to relieve irritation. When suppuration is fully established, the next consideration is, in what direction the contents of the abscess may escape; and here I need not remind you that it is much better that the abscess should open externally, through the integuments of the abdomen, or into some cavity having an external communication, rather than into a shut sac, as in the latter case it is almost certain, and often immediate death. At this period of the case it will be proper to support your patient's strength by allowing him wine, increasing the quantity if the hectic symptoms threaten to run him down, and taking care that his diet be nutritious and of easy digestion. You will also take care to relieve the sufferings and irritation attendant on the disease by the judicious employment of opiates.

When after some time the tumour becomes more elevated and distinct, the pain concentrated in one particular part of the liver, and the abscess is evidently pointing towards the surface, the question then is, whether we shall open it and give exit to the matter, and how this may be best accomplished. That the contents of the abscess should be evacuated as speedily as possible, is true, but the consideration is, how far it can be done with safety. Now, I beg your attention to this point, as it has not been sufficiently attended to in works on the practice of medicine. Recollect what the anatomical condition of the parts is under such circumstances, and that in order to get at the matter, you have to pass through a serous cavity. It is obvious that if you make an incision into the tumour through the peritoneum, and if this be in a state of health, and without any adhesions between its layers in the situation of your incision, you run the risk of having the contents of the abscess effused into the peritoneal sac, and you know that this is

almost of necessity fatal. The condition then for success is, *the circumstance of adhesion taking place so as to prevent the matter from getting into the peritonæum.*

Well, it seems to be a very simple thing to give exit to the matter of an hepatic abscess which presents a distinct pointing. Persons will say, adhesion has formed long since, the integuments are swollen and painful, the matter has crossed the peritonæum and lies close under the skin. Here, however, is a curious fact; of all the serous membranes in the body the peritonæum is that which is least liable to general or partial adhesions, and it is well known with respect to hepatitis with supuration, that you may often have abscess so large as to form a distinct tumour on the surface, which shall be fluctuating, discoloured, and painful, and with all these conditions, so favourable to the notion of matter being actually under the skin, the patient dies, and on dissection we find not the slightest trace of adhesion. If you plunged a trocar or abscess-lancet into this tumour, what would be the consequence?—death by peritonitis. Dr. Graves and I, in our report of the cases of hepatic abscess which occurred in the Meath Hospital, were the first who drew the attention of the profession to this interesting pathological fact, and subsequently to this, Mr. Annesly, who has vast experience in hepatic abscess, stated that in his practice he found that the existence of adhesion between the layers of the peritonæum in the vicinity of the abscess, even after swelling, tenderness, and discoloration of the integuments, is by no means a necessary consequence.

It appears then to be quite certain, that the opening of an hepatic abscess is a matter of considerable nicety, and requiring a great deal of caution. The best mode of proceeding which can be adopted is, in my opinion, that which has been recommended by Dr. Graves, and which is founded on the most accurate pathological views. He makes an incision through the integuments, over the most prominent part of the tumour, and carries it through the cellular substance, fat, and muscular tissue, until the peritonæum is nearly laid bare, and there he stops. The wound is then kept open by plugging it up with lint, and after some time the abscess bursts in this situation with perfect safety to the patient. This operation was performed under his direction, for the first time, in a case of abscess where there was no distinct pointing. It was the first operation of the kind, and every one who witnessed it waited with anxiety for the result. Five or six days passed away without any appearance of matter, but about this period the abscess began to point, shortly afterwards there was a large gush of matter through the wound, and the patient recovered perfectly in three weeks. Since that time the operation has been performed on two patients with success and safety. In the case of one patient it was performed twice at no very considerable interval.

Now, I believe you are all aware, that in cases of deep-seated collections of pus, it is of the greatest importance to remove the obstruction to its exit externally, and that matter will always point towards the place where there is the least resistance. The performance of this operation not only tends to remove the resistance, but also has this advantage, that the existence of irritation in the neighbourhood of the abscess, and immediately over the peritonæum, has a strong tendency to produce adhesion at this point, a circumstance which I was able to verify in a fatal case, in which the abscess had pointed, but never burst. In this case we found on dissection six or seven small tumours near the surface of the liver, without any traces of adhesive inflammation in the peritonæum over them, but over the situation of the tumour, in the direction of which the incision had been made, there was a considerable quantity of organised lymph, and the two layers of the peritonæum were closely adherent. That this effusion of lymph had not been accidental, is rendered probable by the rarity of its occurrence, from not being observed in other cases in which an operation had not been performed, and lastly from the success of the operation in those cases in which it had been employed. I would advise you, therefore, in all cases of hepatic abscess showing a tendency to point, but particularly if this pointing be distinctly towards the surface, to make an incision down to the peritonæum, fill up the wound with lint, and you will often succeed in causing the abscess to break externally, and without any danger to your patient.

With respect to the bursting of an hepatic abscess into the cavity of the peritonæum, I have stated to you before, that it is almost necessarily fatal. I say, almost, because I have seen two cases of this termination, of which one recovered completely from the peritonitis, and the other lived eight or nine days after the discharge of matter into the peritonæum, and on dissection it was found that a process of cure had been going on. The first of these cases was that of a young woman who had a vast chronic abscess. An attempt was made to make this open externally, by destroying the soft parts over it with caustic, but this not succeeding, a lancet was introduced through the eschar made by the caustic. The patient was immediately afterwards attacked with severe pain in the abdomen, and distinct symptoms of peritonitis. As she was very weak and emaciated, Dr. Graves, under whose care she was, gave her opium in full and repeated doses, allowed her the free use of wine and porter; no blood was drawn, no depleting measures of any kind used, but every thing done to support strength and relieve irritation. Under these circumstances (wonderful to relate), she recovered from the peritonitis. She afterwards sunk from the abscess, and on dissection we found that the peritoneal cavity was obliterated, just as the serous investment of the testicle has its opposed surfaces glued

together after an operation for the radical cure of hydrocele. In the other case, the patient lived eight or nine days after the occurrence of symptoms of peritoneal inflammation. On dissection we found a large quantity of transparent lymph effused on the surface of the peritonæum, in the substance of which several large blood-vessels had been developed.

The principles of treatment in a case of this dreadful accident is to support strength and remove irritation, laying aside all antiphlogistics. I am sure that, under such circumstances, the ordinary modes of treating peritonitis are inapplicable and useless. As I shall return to this subject when I come to speak of peritonitis, I shall here merely state, that the treatment of such a case as this is to be conducted upon the same principles as peritonitis, produced by rupture of the intestine, or a perforating ulcer.

Gentlemen, I shall occupy your time briefly in treating of chronic hepatitis. You will find a full description of the symptoms of this disease in almost every book on the practice of medicine, and it is unnecessary for me to detain you with details of this kind. If we are to judge from British practice, chronic hepatitis is a very common disease, and if we look to the practice, it is an affection under which half the community labour. I believe, indeed, that the chronic form of this disease is much more frequently observed in this country than the acute, but still I think it is any thing but a disease of universal prevalence.

I shall not, as I said before, take up your time in stating what you will find in any medical work; I shall merely mention, that in chronic hepatitis we have generally derangement of the bowels, chiefly affecting the stomach and upper part of the digestive tube, and in addition to this we have more or less pain, tenderness, and swelling in the region of the liver, and often dulness of sound over the lower part of the right side. When we meet with this train of phenomena, we say that the patient has the symptoms of chronic hepatitis. But no one under such circumstances could undertake to say whether the patient will die of hypertrophy or atrophy, of cancer or hydatids, of tubercles, or of fatty discharge, or of any peculiar disease of the liver. There is another point, too, of which I am anxious you should be aware. Chronic hepatitis is a disease which has been, and is, frequently confounded with various other affections;—with scirrhus of the pylorus, with chronic disease of the duodenum, with chronic disease of the pleura, and empyema of the right side. There is one circumstance which you should bear in mind when you are in doubt with respect to a chronic hepatitis, that one, two, or three of these affections may occur in connexion with chronic inflammation of the liver. For instance, a patient labouring under chronic hepatitis may have also at the same time empyema and disease of the duodenum. I believe the subject of disease pro-

duced, as it is said, by contiguity in separate organs, has not as yet been sufficiently investigated, and that our knowledge on this important point is extremely scanty.

There are two circumstances connected with this part of the subject, on which I shall say a few words. One common error is that of confounding affections of the heart with those of the liver, and this I regret to say is an error of very serious consequence, and one which is frequently observed in the consultations of medical practitioners. A patient complains of palpitations, a physician is called in, and pronounces the disease to be hypertrophy of the heart; another is called in, and gives it as his opinion that the liver is affected; a third is summoned, and says that both the liver and heart are diseased. In such cases you should always make a careful examination, and weigh well the circumstances of the case in your mind before you venture to pronounce an opinion. In the first place, you are to recollect that organic disease of the heart may produce disease of the liver. Secondly, that disease of the liver (though not so often) frequently brings on morbid affections of the heart and nervous palpitations. Thirdly, that these affections act to one another reciprocally as cause and effect. If a person has disease of the heart, the current of the circulation through that organ is obstructed, and you may have disease of the liver, not as the result of any original affection of that organ, but as the effect of chronic obstruction to the passage of blood through the heart. The consequent congestion and disease of the liver may, in such a case, be reflected on the digestive tube, and this in turn may re-act on the heart. The heart sympathises then with the irritation of the digestive tube; we have nervous palpitations, and if these continue for a length of time, we have the disease of the heart increased. Again, suppose a patient has chronic disease of the liver, causing more or less obstruction to the circulation; the heart begins to sympathise, palpitations commence, go on increasing, and finally terminate in hypertrophy of the heart. The mischief does not stop here; the effects of obstruction extend to the vena cava hepatica, this in turn re-acts on the liver, and we have in this way a curious train of phenomena; first liver disease, then heart disease, and lastly liver disease again. Let me once more impress upon you, that, under such circumstances, you cannot be too diligent in making an examination, or too cautious in pronouncing an opinion.

There is another thing connected with hepatic disease which you should be aware of. A patient, labouring under the following train of symptoms, comes to consult you;—he has pain in the right hypochondrium, loss of appetite, deranged bowels, morbid stools, a dirty bilious hue of countenance, and, in fact, all the symptoms of diseased liver. You examine the liver and find it very much tumefied, in fact its size is so much increased that you

would at once be inclined to say that it was extensively diseased. Now, there are some cases of great tumefaction of the liver accompanied with more or less of the symptoms of hepatic derangement, and yet, in such cases, you may have no disease of the liver at all, at least none of the ordinary forms of hepatitis: these are cases in which there exists, in adults, a persistence of the embryonary condition of the liver. If we compare the condition of this organ in the infant and in the adult, we find many essential points of difference. In the infant it is comparatively large, and as it were hypertrophied; it descends far below the margin of the ribs, and occupies a large portion of the abdominal cavity. On the other hand, if we examine its state in the adult, we find that it has shrunk beneath the short ribs, and that its size and dimensions are comparatively much reduced. Now this physiological atrophy of the liver is a natural and healthy process. There are *certain individuals, however, in whom this change does not take place, and who grow up with the liver bearing the same proportion to the other organs as it did in the fetal condition.* This curious condition is one of the varieties of arrest of development, and is, in almost every instance, observed in those persons whose constitutions present that train of phenomena to which the term *scrofula* has been applied, and which (if I have time) I shall show you is explained, or at least great light is thrown upon it, by the theory of arrest of development. *In such subjects the tumefaction of the liver is by no means a measure of actually existing disease.* If you were to suppose this tumefaction of the liver to be the product of actual recent disease, and proceed to treat the patient in the same way as you would treat a case of hepatitis in the healthy subject, you would not only do no good but, in all probability, a great deal of mischief. I know the case of a gentleman, in the enjoyment of good health, who has this tumefaction of the liver to a very great degree. He is of a thin spare habit of body, with a full, round, and prominent belly; he is pursuing the avocations of an active profession, and yet you will hardly credit me when I say that his liver extends below the umbilicus, and close to the anterior superior spine of the ilium; yet he is very active, and to all appearance a healthy man. You will often meet with this condition of the liver in children who are attacked at an early age with symptoms of *tabes mesenterica*.

At my next lecture I hope I shall be able to finish diseases of the liver, and proceed to the consideration of other affections of the system.

CLINICAL LECTURES

DELIVERED

At the Meath Hospital, or County of Dublin Infirmary, Session 1833-34.

BY PHILIP CRAMPTON, M.D., F.R.S.,
Senior Surgeon to the Meath Hospital, Surgeon-General to the Forces in Ireland, &c., &c.

LECTURE VI.

Burns and Scalds.

GENTLEMEN,—This hospital, situated in the midst of a manufacturing district which is inhabited by the poorest and most profligate part of the population of this great town, is always abundantly supplied with cases of injuries of all kinds, but more particularly with cases of burns and scalds. Parents, obliged to leave their wretched habitations in quest of the means of existence, lock up their unfortunate little children, lest during their absence they should meet with some injury in the streets. The little creatures huddle round the fire on which a kettle (insecurely supported) is left to boil, that the water may be in readiness against the return of the mother, who is to prepare the tea which constitutes their chief repast; the result too frequently is, that the unfortunate children are either burnt by the taking fire of their greasy clothes, or scalded by the over-setting of the kettle. Then we have the consequences of drunkenness and of epilepsy. I am sure I do not exaggerate when I state that more than one-half of all the frightful injuries which we have to treat in this hospital, are the result of drunkenness; but burns, in particular, seem to be the most frequent, as well as the most terrible punishment of this besetting vice of the poor of this city. In the stupor, rather than the sleep, which succeeds to the excitement of intoxication, persons often remain insensible to the action of heat, until it has caused the complete disorganisation of the soft parts down to the bone. There is at this moment in the accident ward, a sweep who lay down so close to the fire, that the side of his face, chest, and arm are burnt to a coal; nothing can save this wretched man from an agonising death; and, lastly, we have the frightful burns and scalds to which persons are so much exposed who are employed in breweries, and other branches of manufacture which are carried on so extensively in the Liberties. It is not surprising, therefore, that this hospital should be a kind of *dépôt* for burns, or that the management of this description of injuries should have engaged a good deal of my attention during the thirty years I have been connected with the institution.

Burns share the fate of all diseases and injuries which, in consequence of their complication with severe and frequently irreparable organic lesion, are least under the control of medical treatment. They are considered by the people in general as peculiarly the subjects for

popular remedies, and it is quite astonishing with what undoubting confidence many sensible persons continue to believe (or, at least, to assert) in opposition to the plainest dictates of reason and experience, that they possess an infallible remedy for burns. The utter absurdity of looking for a specific for burns, or of supposing that any one plan of treatment can be applicable to all injuries of this description, will appear from this single consideration, that under the head of burns is included every degree of lesion, from a slight superficial inflammatory action of the skin, to the total disorganisation of all the soft parts, accompanied by a peculiar affection of the nervous system, and of the digestive apparatus.

For the purpose of more conveniently treating a subject so vast, and embracing such a variety of details, it is necessary to adopt something like a classification founded on the *degree* as well as the *kind* of the injury. Such a classification must necessarily be imperfect, because in a great majority of cases, you will in each subject find every degree of lesion according as the parts were more or less exposed to the action of heat. Nevertheless, the classification, imperfect as it is, will be found useful in practice, and all systematic writers have accordingly divided burns into certain classes. Heister and Callisen have divided them into three, Dessault into four, and Baron Dupuytren into six. For all practical purposes it will be sufficient to divide them into five classes.

In the first class, the inflammation of the skin is slight and superficial, presenting an erysipelatous-like blush, unaccompanied by bullæ or blisters, and involving no apparent destruction of tissue. This is a very common form of burn, and is generally caused by a very transient application of heated air, or of water not above the temperature of 150° ; but when water above that temperature is applied to the skin, even for a few seconds, it produces detachment of the cuticle more or less extensive. If its application be partial and momentary, you will have bullæ, or small vesications formed; if more extensive and longer continued, it is attended by detachment of the whole of the affected cuticle, so that if you attempt to pull off the stocking of a person who has received a scald of this description, the whole of the separated cuticle comes away with it. The first class of burns, then, consists of simple erysipelatous-like inflammation of the skin, produced either by water not above the temperature of 150° , or by a contact with heated air momentarily applied, and insufficient to give rise to vesications or bullæ.

The *second* class of burns comprises all injuries of this description, in which there is a detachment of the cuticle, in addition to the inflammation of the skin; this detachment you know is caused by the effusion of serum from the over-excited capillaries of the true skin. In the first class you will remember that we have no separation of cuticle; in the second it forms the

most prominent feature of the lesion, and you will find this distinction useful, because the treatment which is applicable to one cannot be employed with advantage in the other.

In the *third* class, we place all those burns in which the cuticle is detached, and the superficies of the true skin disorganised, as well as the rete mucosum which lies on its surface. This disorganisation, or death of the skin, is necessarily succeeded by the detachment of a slough, the thickness of which corresponds with the depth to which the disorganisation has extended. This destruction of the surface of the true skin constitutes the essential character of this description of burn, and is the cause of a peculiar train of symptoms, both local and constitutional, which are wanting in the two former classes. The local symptoms are, the occurrence, on the third or fourth day, of a margin of inflammation round the disorganised portions of the skin, which is followed by suppuration, and the detachment of sloughs from the twelfth to the twentieth day, according to their thickness, and the structure of the parts they involve. The constitutional symptoms are the symptomatic fever invariably attendant on acute inflammation, when it affects an extensive surface, and terminates in suppuration; this is what the French pathologists call the "*fièvre éliminatoire*." With this is usually combined great nervous irritability, and a very disturbed condition of the digestive organs. The cicatrices which remain after a burn of this kind, are always white, thin, shining, and insensible; they do not give rise to contractions, and their whiteness and insensibility are owing to the destruction of the rete mucosum, and of the beautiful vascular and nervous tissue which lies on the upper surface of the true skin. This injury may be produced by boiling water, or by the transient application of flame, as when a light muslin dress takes fire, but is torn off before it has lain even for a moment on the skin.

In the *fourth* class of burns, there is disorganisation of the whole depth of the skin, including the cellular texture beneath. Here you have an exceedingly dangerous form of burn, in which the process of reparation is tedious, and often imperfectly performed, and where cicatrisation never takes place without considerable contraction of the affected tissues. These contractions, when the result of an extensive burn, frequently deprive the patient of the use of the injured limb, particularly when the burn happens to be near the elbow or knee-joints. In the one case the leg is sometimes drawn up and fastened as it were to the thigh; in the other, the fore-arm is bent on and for some extent united with the arm. Here the constitutional symptoms keep pace with the severity of the local injury; the nervous system in particular seems to suffer, and if a large surface of the skin be destroyed, the powers of life are rapidly exhausted, and death usually takes place within the first three or four days.

The *fifth* class of burns includes those in which the skin, cellular substance, and perhaps the muscles are reduced to the state of an eschar, their texture being wholly destroyed. This is one of the accidents which so often result from drunkenness; a man having drank to excess, sits or falls down by the fire in a state of utter helplessness, and is found in some time after, resting against the grate, with a portion of his arms or face burnt to a cinder. Burns of this description, however, are usually caused by the clothes taking fire, particularly if the person rushes through the air in quest of assistance. The skin, when examined, is found to be tense and dry, of a pale brown colour, inclining to yellow, and when it presents this appearance you may be quite sure that it is disorganised through its whole depth, and must separate from the subjacent muscles before an attempt can be made towards reparation; that this separation is always attended with suppurative fever of the most severe kind, and consequently, if the burn be extensive, it is invariably fatal, either immediately, from the impression made on the nervous system, or subsequently from the irritation attendant on the separation of the sloughs. In children such injuries are often succeeded by fatal convulsions.

In the generality of cases, injuries belonging to two or more of these divisions co-exist, the classification is therefore imperfect, but the rule is to take the greatest degree of the injury as the essential character of the affection. Now, the greatness of the injury, that is to say, the pain and danger attendant on it, depends to the full as much on the extent of the surface affected as upon the depth of the injury. The pain, which attends a slight detachment of the cuticle, is often as great as that which accompanies a more serious burn; and a burn or scald, with a slight detachment of the cuticle, when extensive, is more dangerous than an injury which destroys the texture of the soft parts to a considerable depth, but which is of comparatively limited extent. We used to have many instances of these superficial but extensive lesions of the skin among brewers' men in the Old Hospital on the Coombe; but whether it is that some means have been adopted to prevent the liability to such accidents, or whether it is that the men are more careful of themselves, we very seldom meet with them of late. I remember a case of this kind which happened some years since. A brewer's man, while employed about the mash tub, slipped and fell into a large quantity of mash at a high, but not the boiling, temperature. He was pulled out on the instant and brought to hospital in a state of great depression. The cuticle was scarcely detached from any part of the surface of his body, but the vital powers were very much depressed; his countenance was ghastly, like the little boy now in the accident ward, and he constantly cried out that "he was perishing with cold." His pulse was small and rapid, and he sur-

vived but a few hours. Many persons have died under such circumstances in this hospital, showing that irritation, affecting the surface extensively without causing sensible disorganisation, is to the full as dangerous as the total disorganisation of a part of limited extent, if it does not involve some organ, the healthy action of which is essential to life. Always give a guarded prognosis, therefore, in cases of extensive scalds, particularly in children, even though the cuticle should not be extensively detached, as such an injury usually proves fatal by causing convulsions.

The next thing which modifies the nature of a burn, or scald, is the place on which the injury is received. A burn on the upper or lower extremities is much less dangerous than one of the same extent and depth on the face, neck, chest, or abdomen. Burns on the chest are, *ceteris paribus*, more dangerous than on the belly.

With respect to the treatment of the first class of burns, where persons are exposed to the contact of water below the boiling point, or to steam, or to the momentary impression of flame, and where the injury done to the skin does not amount to actual separation of the cuticle, the best thing which can be done is to put the burned or scalded part *immediately* into a vessel filled with cold water, and to keep it there until the pain ceases. This is one of the simplest and most effectual modes of treating this form of burn, *except in cases where the surface is very extensive*, and the injury received has given a shock to the nervous system, as evinced by general shivering and a sinking pulse. In these instances it is inadmissible, but under all other circumstances it proves extremely useful, and I know of no better, or even equally powerful remedy.

I remember a case of this accident (attended with rather singular circumstances), which occurred while I was living in Dawson-street. I happened to be on the top of a ladder, which I had placed against the garden wall, while in pursuit of a monkey which had broken its chain, when I heard a piercing shriek proceeding from the kitchen of my neighbour, Mr. Hope's house. Concluding from the cries, that something dreadful must have happened, I dropped instantly from the garden wall, and in a moment was in the kitchen. Here a very alarming scene presented itself; the servant-maid had just filled a large washing tub, which lay on the floor, with hot water, and a little child, of about three years old, who had been running about the kitchen, had fallen head-foremost into it. Just as I entered, the servant had pulled the child, yelling and screeching with agony, out of the tub. Without waiting to make an examination of the scalded parts, I snatched the child up in my arms, and, running out into the area, plunged it over head and ears into the cistern, and continued to dip it from time to time, plunging the head and face under water each time. The child continued to scream, but it was obvious that the

pain of the scald was abated by the submersion. I then, without taking it out of the water, cut off its clothes, and had it removed to bed, where it was kept constantly covered with clothes dipped in cold water, until it began to complain of cold. Next day the child was running about as usual, and, with the exception of a few small blisters on the chest, neck, and arms, had not the slightest trace of the injury remaining. It was one of the most rapid cures I have ever witnessed, and I have no doubt that the rapid recovery is in a great measure to be attributed to the *instantaneous* submersion in cold water, and to the care that was afterwards taken to keep the surface cool. I must add, however, that the result would not have been so favourable if the water, into which the child had fallen, had happened to be at, or even near, the boiling point. This mode of treatment is applicable exclusively to cases in which it can be employed *instantaneously, and where there has not been time for the powers of life to be exhausted, or the cuticle to be extensively detached*. No man in his senses would think of plunging an unfortunate creature, deprived of a great portion of his cuticle and shivering with cold, into a vessel of cold water. I believe that, in such circumstances, all that can be done is to place the patient on a bed thickly covered with fine flour, to give him a cordial drink with a full dose of opium, and to await the setting in of re-action. This once established, bleeding, general or local, will afford the best chance of averting the tendency to inflammatory affections of internal organs (particularly of the stomach and intestines) which, in such cases, seem to be the immediate cause of death.

In the second class of burns your treatment must be regulated in a great measure by the constitutional symptoms, particularly where the surface of the burn is extensive. When a large quantity of hot water falls upon a person, as frequently happens in the case of children,—as for instance, when one of these little creatures puts its hand upon a table and overturns a cup of scalding hot tea upon its breast, the fluid runs down the neck, breast, and belly, and, confined by the clothes, the heat penetrates deeply, and thus causes an injury of the third class, that is to say, a scald in which the mischief extends to half, or a third, of the depth of the true skin. Now, when a lesion of this character happens to be very extensive the nervous system receives a severe shock; there is, from the excessive pain, a rapid exhaustion of the vital power, as evinced by shivering and an extremely rapid but weak and tremulous pulse. Under such circumstances no one would for a moment think of applying cold; such an application would probably extinguish life altogether. You first cut away the clothes, then place your patient on a bed covered with fine flour to the depth of an inch or two. Let every injured spot be covered with a thick layer, and place pillows or bolsters on each side of the child, so as to

support the weight of the bed-clothes. Let the dusting with flour be repeated as often as the moisture from the scalded surface begins to appear, give warm drinks with a few drops of laudanum until re-action begins, and then (if necessary) have recourse to bleeding, but the necessity for bleeding seldom occurs before the evening of the third day.

I attended some time ago a child in Merrion-square, who met with a very severe accident of this kind. He was standing by the breakfast table, near the edge of which a bowl, containing a large quantity of boiling water, was placed; he put up his hand and pulled down the bowl, the water streamed all over his neck, breast, belly, and thighs. To make the matter worse, his attendants, in attempting to strip off his clothes, tore away the whole of the cuticle covering his breast. I saw him a few minutes after the accident, and had a bed of flour made, in which he was placed, or rather immersed; and, having called up the cook, I desired her to bring her dredging box, and dust him over, just as she would dredge a fowl, until every scalded spot was covered with a thick layer of flour. In this way the child was kept for three weeks, care being taken to add fresh flour every day to absorb the pus; and whenever the flour became hard, and formed crusts, so as to give the child inconvenience, if they were not detached by the discharge, I removed them with my finger. About the fifth or sixth day, inflammation began to appear about the sloughs; and then I commenced with the application of leeches to the skin in their vicinity, a practice which I have for some years adopted, and to which I attach the utmost importance. The moment you see a red border formed round the sloughs, which is generally on the fourth or fifth day, apply a few leeches round that border; the constant oozing of blood will prevent any excess of inflammation, and the separation of the sloughs will go on favourably. I think I have seen many persons saved by this treatment.

I need scarcely warn you in this hospital against the antiquated practice of applying emollient poultices for the purpose of hastening the detachment of the eschars; the effect of such treatment is to increase the suppuration, already too profuse, to cause the eschars to putrefy, and produce the foulest and most irritable sores you can possibly conceive. Spirituous washes, with the addition of a small quantity of the chloride of lime, are infinitely preferable. Boerhaave, who was himself a sufferer from a severe and extensive scald, with sloughing of the skin, describes very graphically the miseries he endured from the use of emollient poultices. Exhausted by his sufferings, and annoyed by the stench, he at length determined to dry up the eschars, and with this view applied spirituous washes and drying powders. He states that the relief was instantaneous, that the new skin crept in under the drying eschars, and that these, sepa-

rating like chips, left the surface perfectly healed beneath.

I need not remind you here, that in all cases where the nervous system has received a severe shock, a good deal of attention must be paid to the constitutional treatment. Opium must be given in large and frequently repeated doses, until you have thrown your patient into such a state of narcotism, as will subdue the nervous irritability, relieve pain, and procure some tranquil sleep. Nothing tends so much to exhaust the powers of life as long-continued irritation, sleeplessness, and pain; and there is nothing, in such instances, of such unequivocal value as opium, which, by controlling or removing these causes of exhaustion, gives nature time to rally and bring forward all the conservative powers of the system.

The bowels also must be attended to; and we should be careful in ascertaining the state of the digestive tube, for many cases of this description are accompanied with more or less of a gastro-enteritis. It is certain, at least, that on dissecting the bodies of persons who have died from the effects of extensive burns, large and numerous patches of inflammation have been discovered in the mucous surface of the intestines; and this should make us cautious in administering purgatives, particularly of the drastic kind. If the bowels are constipated, employ enemata, or give some very mild laxative, such as the electuary of cassia, or a small quantity of castor-oil; and with the view of relieving the gastric irritation, and diminishing fever, you may prescribe barley-water with gum arabic, effervescing draughts, and gentle diaphoretics. This treatment is to be continued until suppuration commences, and then a different mode of treatment is to be adopted. You are then to support the strength by nutritious food, wine, infusion of bark with sulphuric acid, the sulphate of quinine, and other tonic remedies.

There is a mode of treating burns of the first, second, and third degrees, which has lately been recommended, and, as it would appear, practised with much success by MM. Velpeau and Brettonneau, of which I cannot speak from experience; but, as I do not wish to pass over any thing which promises to be of advantage in a practical point of view, it is my intention to try it on the first case of this form of injury that comes to the hospital. It consists in making pressure by means of a bandage, from the toes to the hip, for example, where one of the lower extremities is the seat of injury, which is to be kept moist by a weak solution of acetate of lead or cold water. But the chief thing in this mode of treatment is pressure, which, according to these authors, abates pain, prevents effusion of serum into the cellular substance of the limb, and limits inflammation. Even though sloughing of the parts may take place, they persevere in keeping on the bandage, merely taking the precaution of washing off the discharge, and cleaning the sloughs once or twice a-day.

When the sloughs have separated, you generally experience a great deal of difficulty in managing the sores which remain; they are covered with unhealthy, irritable granulations, endowed with such exquisite sensibility, that the weight of the lightest dressing, the application of any substance, even of the most decided anodynes, or the slightest exposure to the air, gives very severe pain. Under these circumstances, the best thing you can do is to brush the diseased surface lightly all over with a strong solution of nitrate of silver (say twenty grains to the ounce of distilled water), and then you may dress them with the lapis calaminaris ointment, or with the powder sprinkled through a hair or muslin sieve. This forms a good dressing: it absorbs the discharge, dries up the surface, and hastens the process of cicatrisation. It will be necessary to apply the nitrate of silver three or four times before the irritability of the sore is completely removed; and you will find, that though it gives considerable pain for the moment, the relief which follows its application is so decided, that the patients will frequently call for it.

In the fifth class of burns, very little can be done. Here you have complete disorganisation of the skin, cellular tissue and muscles down to the bone, and frequently the bone itself is involved in the same mischief. Under such circumstances, all that our art can effect is to keep the inflammation within bounds while the process of separation is taking place, and to support the strength by generous diet, wine, and tonics; and, lastly, to make such applications to the sores as circumstances may require. Sometimes you have to apply soothing and sometimes stimulant applications; at one time opiate ointments, at another nitrate of silver, but never poultices; they give great pain by their weight, and by the heat they keep up in the parts, confining the discharge, and giving rise to that peculiar odour which tells you at once that there is an ill-managed suppurating burn in the room. One of the best applications in these cases is camphorated spirit of wine, with a weak solution of the chloride of lime or soda, which have the effect of destroying the insufferable odour, and cleaning the surfaces of the sores.

I remember a very curious instance of this form of burn, which occurred in the old hospital on the Coombe. An old woman was admitted with a very deep and dangerous burn. It appeared from the history of the case, that she had fallen asleep by the fire in a state of intoxication, and did not wake until the whole hand and fore-arm were burned as black as a coal. We waited until the line of separation had taken place, and then proposed amputation, to which she would by no means consent, saying, that if she was to die, she would rather go to the grave with her arm as it was; and that she was neither young nor strong enough to undergo the operation. Finding it useless to attempt to convince her of its necessity, we

kept her in the hospital, and watched the case to see what would happen. At the end of the fourth month nature performed the operation,—the fore-arm was found lying by her side in the bed, detached from the rest of the body, and that without the loss of a drop of blood; for, long before the bone gave way, the skin had formed over the living surface of the stump down to the bone itself. She had been using all the time a lotion composed of the camphorated spirit of wine; and the affected part had become as dry and as sapless as a mummy.

I have said nothing of the treatment of burns by oil of turpentine externally, and stimulants internally, as proposed nearly thirty years ago by Mr. Kentish. The practice arose out of a theory which is altogether fanciful, and this furnishes a strong *primâ facie* objection to the practice. But the practice itself has fallen into disuse, a circumstance which would not have happened, had it been productive of any real advantage. We gave it a fair trial in this hospital several years ago, and at length rejected it as most painful and inefficient.

With respect to the use of raw cotton, you saw it fairly tried in the case of the child in the accident ward. One leg and thigh was dressed with flour and the other with cotton; the flour leg got so much better than the cotton leg, that we were glad, after a week's trial, to rest content with the use of flour only.

Among the worst consequences of burns are those contractions of the skin which frequently bind the fore-arm to the arm, the leg to the thigh, and the chin to the thorax. It depends, however, very much upon the care of the surgeon whether his patient experiences these calamities or not. When an extensive burn or scald involves the surface of the hand and fingers there is much need of care and attention during the process of healing; and if you attempt to prevent them from adhering by the interposition of pieces of lint, you will certainly be disappointed. The best plan in this case is, to take the requisite number of straps of leather cut into an hour-glass shape, and spread with adhesive plaster; put the narrow part of these straps between the fingers, draw the ends up and fix them to the arm. Besides these, you put pledgets of lint smeared with oil between each finger; lay the hand on a splint, and bind it down with a roller: by doing this you will prevent contraction. The same thing is to be done in the case of a burn involving the elbow joint; a broad piece of leather spread with plaster and placed over the joint, so that the fore-arm cannot touch the arm, and keeping the limb extended on a splint will prevent deformity. If this be not done you will have the fore-arm contracted, and united to the arm by a tense, white, organised cicatrix, which is thick and cord-like at the top and thinner in the middle. In order to remove the deformity, you must divide this cicatrix, extend the arm, and if you

wish to prevent a recurrence of the mischief, you must dissect away this angular portion which forms the cicatrix, commencing where it begins at the fore-arm, and proceeding to where it terminates in the arm. This operation, however, requires a good deal of care; the contraction of the cicatrix draws up the blood-vessels, and you must carry on your dissection with caution, and look for the vessels, so as to avoid wounding them. When you have dissected out the cicatrix, bring the sound skin together with strips of adhesive plaster, and you will, in many instances, succeed in preventing the deformity. You will find a great many valuable observations on this subject in Mr. Earle's paper in the *Med.-Chirurg. Transactions*. In cases of burns of the neck, the chin is sometimes united to the sternum, the lower jaw is drawn down and fastened to the breast, and the mouth remains constantly open, constituting one of the most frightful deformities which it is possible to imagine.

After the lecture a patient was brought into the hospital under the following circumstances:—He stated that he was a hackney car driver, and aged about thirty-five years. Five days previously he was seized with severe pain in the back of the thigh, and on the following day he was unable to straighten his knee. Since the commencement of the pain he has felt "a great sickness over him," and has never enjoyed a single hour's sleep. He looks exceedingly ill; his pulse is small and frequent; there is a light erysipelatous blush over the integuments at the back of the thigh; the whole limb appears to be somewhat swelled; and Mr. Crampton pointed out to the class, that it was tense and hard at its posterior part, a little above the ham.

"This, gentlemen," said Mr. Crampton, "is a most important and instructive case. It is an instance of acute deep-seated abscess of the thigh, with its constant attendant—erysipelas of the skin. I shall give you a particular lecture on this case; but at this late hour all that I can do is to show you what is required for the safety of the patient. The matter, which has just been formed, is lying deep beneath the fascia, and even below the superficial muscles. If art were not to interpose, the suppuration would extend upwards and downwards among the muscles, producing intense pain; and if the man were (as he appears to be) of a bad constitution, the inflammation would assume the erysipelatous character, in which, you know, the adhesive process is deficient, and spread all through the limb. The cellular membrane, deprived of its vitality, would form sloughs immersed in a sanious suppuration; the skin, detached from the superficial fascia, would become pale, then purplish, and this would be the precursor of its sloughing; eschars would form on it from its partial mortification, and when these separated (if the patient survived the mischief) it

would be found that the openings led into an immense cavity filled with unhealthy pus, and traversed by muscles altogether deprived of their cellular texture, and appearing more clean than you have ever seen them on a dissecting table. Concurrently with all this terrible local mischief, we should have suppurative adynamic fever of the worst description, profuse perspirations, diarrhoea, and not unfrequently purulent depositions in the lungs and liver. I need scarcely say that few indeed have a constitution capable of holding out under such accumulated sufferings. Accordingly, phlegmonoid erysipelas of this kind is not only one of the most painful but one of the most fatal occurrences which we ever encounter; and here we have an illustration of the truth of the aphorism of Hippocrates respecting erysipelas:—"Ex erysipelate putrido, aut suppuratione malum." You will observe, that the word "putrido" is used to express the sloughing and putrefactive process which characterises the suppuration of erysipelas, as distinguished from that of phlegmon. Children escape oftener than adults; but I have very seldom indeed seen a man after fifty who has survived phlegmonoid erysipelas of a lower extremity, where the disease had got extensively into the intermuscular cellular membrane. The successful management of this disease I look upon to be the greatest triumph of modern surgery. You all know how much stress I have ever laid on the necessity of early and vigorous measures in the treatment of this affection; and I trust that the present case will add one more to the many successful cases which we have had of this disease since our session has commenced. Among others, the boy in the large clinical ward, with phlegmonoid erysipelas of the knee and thigh from a wound; the man with a similar affection of the fore-arm, from a wound on the elbow; the woman with erysipelas of the fore-arm and arm, from a slight contused wound of the elbow, on whom I operated last week, and whom you saw this morning among the externes nearly well, are all cases of the successful treatment of this disease.

It affords me great satisfaction in having an opportunity of rendering that justice to Mr. Copeland Hutchinson which some of his own countrymen have denied to him. To him we are *exclusively* indebted for this great improvement in the treatment of erysipelas. Like all great improvements, it was at first met by a denial of its utility, and then by attributing it to somebody else; but I have no hesitation in thus publicly offering my acknowledgments to him for one of the most valuable improvements which have been made in the practice of surgery within our times.

The case before us, you will observe, is not one of phlegmonoid erysipelas, properly so called: it is a case of *deep-seated intermuscular phlegmon*, accompanied with erysipelas of the skin and subjacent cellular tissue, in consequence of the inflamed and tense state of

the fascia. But in a constitution like this man's, broken down as it is by intemperance, the true phlegmonoid erysipelas would in all probability arise, if the abscess were not opened, and the tension of the inflamed fascia relieved.

Mr. Crampton having laid the man on the table in a prone position, made an incision six inches long over the posterior aspect of the lower third of the thigh. The cellular substance, which was now exposed, was loaded with a reddish coloured serosity. Mr. C. then slit up the fascia to the same extent, and laying aside the knife, he slowly insinuated his fore-finger between the muscles, just above the popliteal space, until he reached the cavity of the abscess, and this did not occur until his finger was buried as deep as it could go.

"Now," said Mr. Crampton, "I have reached the matter;" and on withdrawing his finger, about eight ounces of thick cream-coloured pus gushed from the wound. A thin dossil of lint was interposed between the lips of the wound, and the man was carried to bed. He was ordered some purgative pills, and an effervescing mixture made in an infusion of cinchona.

Dec. 2nd.—The man is free from all complaint, and the wound is healing rapidly.

ESSAY ON THE STRUCTURE AND FUNCTIONS OF THE SKIN.

BY MM. BRESCHET ET ROUSSEL DE VAUZEME.

Read by the former to the Académie Royale des Sciences, on their sitting, 27th of Jan., 1834.

Rerum natura sacra sua non simul tradit aliud hæc ætas aliud quæ non subibit, adspiciet.—*Senæger Nat. Quest.* lib. viii. c. cxxxv, xxxi.

(Concluded from page 340.)

We designate by the name of epidermis the entire corneous substance which invests the cutis. This epidermic matter is applied on the cutis in the same manner as a mask of liquid plaster with which it is usual to cover the face of a person when modelled, and which becomes adapted to the inequalities of this surface. The totality of this layer has been already described under the name of *reticular membrane of Malpighi*.

We consider it as formed of two portions; the one occupies the folds of the cutis, and adheres to them by prolongations furnished by the excretory tubes belonging to the organs which elaborate the colouring and corneous matter, and it is from it that the horny substance is derived. On endeavouring to separate this

layer, a somewhat forcible resistance is experienced, since it adheres to the cutical furrows by radicles which appear to project into it. Nevertheless it occasionally separates freely, as if it were not applied to the bottom of these folds; it presents apertures for the transmission of lymphatic canals.

The second portion of this substance occupies the intervals between the papillæ, and is deeply prolonged around the sudoriferous and lymphatic canals in these interstices. This layer offers towards the apertures a species of sheath, into which the nervous papillæ obliquely penetrate.

Prominent, slightly concentric, and parallel lines, which separate the furrows, are marked on the external surface of the epidermis. On examining these lines by means of a magnifying-glass, they alternately present little papillary eminences, and slight depressions, which correspond to the orifices of the hydrophorous canals. There are in general from four to six on each line. It is easily perceived that these prominent lines are formed of scales, which overlap each other in such a manner, that in the movements of contraction, for example, these scales advance upon each other, in the same way as those of a fish or reptile, whilst by the movement of extension they separate, and leave the bottom of the furrows exposed.

The skin presents this arrangement, especially at the points where folds are usually produced, as in the fore-arm, ham, groin, &c. The corneous substance in man is of a dull white colour, transparent, elastic, and essentially hygrometric. This layer being much thicker in the whale, can be studied with great facility. This epidermic tissue (and we thus name all the corneous matter which is situated above the cutis, which is ordinarily described as the epidermis mucous, or reticular substance of *Malpighi*) is shining, spongy, and of a more or less deep gray colour when regarded in its totality. Viewed with the naked eye, two layers are perceptible, the one formed by lamellæ parallel to the plain of the dermis, the other composed of straight fibres perpendicularly placed between the cutis and exterior layer. The white threads of the nervous papillæ, enveloped in their sheaths, appear through the thickness of this dark gray tissue, and the inferior surface of the horizontal layer seems pierced with apertures or depressions,

according to the height at which this layer for the passage or reception of these little papillary cones may be considered.

In order to analyse the epidermis, it is necessary to select one of its perpendicular fibres, and place it in the focus of a lens upon a moistened glass. It is then distinguished that this fibre is composed of a succession of little lamellæ, which are scale-shaped, imbricated, and situated on a very delicate cellular network. These scales are detached with great facility, and it is them that stain the water black under the form of granulations. Each scale, separately considered, possesses the form of a racket or blunt spatula, and presents a narrow and whitish pedicle; the two surfaces are tinged with black. The point at which the horny substance commences is distinctly recognised in the cetaceæ, on account of the black tint of this matter cutting with the whiteness of the dermis.

The development of this tissue is effected from within to without, and is first visible under the appearance of a mucous and almost liquid matter, which gradually solidifies and thrusts before it the superior layers which are already distinctly disposed in scales. The most external layers are, therefore, the most ancient and compact.

Although we have admitted two layers in this epidermic body, one only in reality exists. The following is the cause of this illusion: the vertical fibres which arise from the surface of the cutis become inclined, shortly after having traversed a certain space, and finally become horizontal, the scales which they constitute naturally form what is in general called the epidermis, which organ is only, according to our idea, the most superficial layer of the corneous tissue. The sudoriferous canals curb themselves in the same way as the scaly fibres of the horny tissue, and as they open more or less obliquely beneath the last scale of the horny tissue, their orifices are only perceptible on elevating this scale. An attentive examination of all the shapes that the epidermis assumes, has taught us that its differential forms are merely owing to this mode of production, and that all are formed by the elementary fibre, which we have just described. This corneous layer, which comprehends the epidermis and rete mucosum of various authors, is constituted in man in the same manner as

in the cetacea. Two elements which are furnished by two different organs of secretion, enter into the composition of these parts; the one employed in the elaboration of the colouring matter, the other in the production of a substance apparently mucous. We have also detected the existence of twigs perpendicular to the cutis, which gradually incline, in order to become horizontal on approaching the superficies. The existence of scales was equally verified, and if our limits would enable us to make known a long series of researches, we could clearly demonstrate that the skin of all vertebrated animals which have been submitted to our inspection presents a similar organisation.

6th. Organs which secrete the colouring matter, or chromatogenous apparatus. This little apparatus is situated at the exterior part of the cutis, at the bottom of the furrows, and above the prominent lines of papillary bodies. Its superior portion is surmounted by a great number of short excretory tubes, which terminate at the bottom of the furrows, and pour their colouring matter into this situation. Its inferior surface is roughened by capillary vessels in connexion with the excretory canals of the glands which secrete the liquid matter, the condensation of which constitutes the horny substance, or corpus mucusum of Malpighi. The structure of this secretory organ appears to be areolar, spongy, and resistant; its own peculiar parenchyma and excretory canals are sometimes of a florid red colour, being essentially vascular. They form a limit which the arterial system cannot surpass, this system ceasing to exist at this point. On lacerating this tissue, an infinity of small filamentous tubes are discovered, from which scales or colouring granulations escape. This reservoir exists in no other parts of the cutis.

This parenchymatous tissue may therefore be considered as a glandular organ, formed of a substance peculiar to itself, which is penetrated by capillary vessels, and from which arise excretory ducts, terminating at the same point as those of the gland destined to secrete the horny matter. These little canals or ducts belonging to the organ which elaborates the colouring matter, pour this pigmentum into the substance which forms the horny layer, or corpus mucusum of Malpighi.

In the skin of the cetacea it is distinctly

seen that the dark colouring matter is excreted a little before it appears on the exterior of the cutis; that is to say, that at about half a line before its exit it is found enclosed in a capsule, on whose surface are observed little whitish papillæ, which are closely embraced by this membrane: these are the excretory canals belonging to the glandular chromatogenous apparatus or organ which secretes the colouring matter.

Conclusions.

If this cursory recital has been correctly understood, it would appear to result, from our long and difficult labours, that we have discovered numerous conformations of the highest importance, which will produce greater precision and exactitude in the appreciation of the laws which govern innervation, perspiration, or cutaneous exhalation, colouration of the skin, production of epidermic tissue and their appendages.

Thus we have endeavoured to prove, first, that there exists in the skin an apparatus adapted to the secretion of perspirable matter, composed of a glandular parenchyma which elaborates this liquid, and of ducts by which it is exhaled. These excretory canals are arranged in a spiral manner, and open very obliquely beneath the scales of the epidermis. Secondly, that the organs of absorption differ in some respects from the lymphatic vessels or veins, with which they however appear to communicate. These organs present the form of transparent ducts, which possess an extreme fragility, and form ramifications or little communicating loops, in which we were unable to detect any terminal orifices adapted to absorption. This circumstance inclines us to believe that this function is incapable of being performed by suction, but results rather from imbibition, or from a mechanism analogous to that of endosmosis. Thirdly, that the medium in which these canals are distributed is a substance produced by true secretion, which being strongly hygrometrical, forms a body, by means of which the phenomena of that which we still call absorption are capable of being effected. This absorption is more promptly and easily performed by the mucous surfaces, only because in these tissues the mucosity, which we compare in many respects to the epidermis, is less dense, and more readily mixed with the liquids which are required to

be absorbed. Fourthly, that the papillary bodies are essentially nervous, and that the filaments, which enter into the composition of each papilla, do not terminate in the formation of a bundle, in which each twig would be free and isolated, but the ramusculi appear to present terminal loops or arches. Fifthly, that the papillæ are enveloped by a distinct membrane, and by a layer furnished by the corneous substance of the epidermis. Sixthly, that sanguineous vessels, much less voluminous than the nervous filaments, penetrate this substance. Seventhly, that the different horny layers of the epidermis constitute a peculiar apparatus composed of an organ of secretion, and of a product arranged in fibres, which are at first perpendicular to the cutis, but which afterwards become horizontal. These fibres or little twigs result from a superposition of small scales, and the epidermis, properly so called, is only the extremities of these fibres, which are the most distant from the cutis. Eighthly, that absorbent canals and nervous papillæ are expended in this epidermic substance formed by squamous prolongations. Ninthly and lastly, that, independent of the secretory apparatus situated in the epidermis, there exists in the skin, towards the external surface of the cutis, a small apparatus for the secretion of the colouring matter.

Foreign Medicine.

Incision of the Urethra for Fistulæ.

BY M. VIGUERIE.

A PATIENT affected with numerous urinary fistulæ having allowed a portion of a bougie to escape into the bladder, M. Viguerie, sen., surgeon in chief to the Hôtel Dieu de Toulouse, performed the perineal section. The urine flowed through the wound for forty days; but, after that time, it passed through the urethra; the fistulæ were cured spontaneously. This cure, effected by chance, led M. Viguerie to think that an incision upon the urethra might be had recourse to in some cases of obstinate fistulæ; and he has accordingly made trial of this operation in two cases. The subject of the first operation had long suffered from fistulæ, which had obstinately resisted the introduction of a sound. For three weeks after the incision was made the urine escaped by the wound, after which it returned to its proper channel: the fistulæ

rapidly got well, but the wound was seven months cicatrising. The second patient is still under treatment in the hospital. New facts are necessary before any judgment can be formed on the merits of the operation; but the disease, for the cure of which it is recommended, is so obstinate and distressing, that any new suggestion for its treatment is deserving of favourable consideration.

Colchicine.

This alkali is stated by MM. Geiger and Hesse, who have succeeded in obtaining it, to crystallise in slender spires, and to possess an extremely bitter taste. Taken into the nostril it does not excite any irritation, whilst the least portion of veratrine causes violent sneezing: it is, however, equally poisonous with the latter, as the following experiment sheweth. A tenth of a grain, dissolved in a small portion of weak alcohol, was given to a cat about six weeks old; in a short time froth appeared about the animal's mouth, and in the course of an hour it was violently purged; it then vomited, tottered in its walk, fell, rolled from side to side, uttered moaning sounds, and appeared agitated with convulsive movements. These symptoms increased in severity, and caused death at the end of twelve hours. The intestinal canal was found inflamed, and there was effusion of blood throughout its whole extent. For the purpose of comparing the effects of this substance with veratrine, the twentieth part of a grain of the latter was given to a cat a little younger than the former;—the animal was affected in the same way, but more rapidly, for it died in ten minutes. The superior part only of the oesophagus was found inflamed, an appearance which was not observed in the cat poisoned by colchicine.—*Journal de Pharmacie.*

Hyoscyamine.

It is from the seeds of the *hyoscyamus niger* that this substance, which is formed in transparent needle-shaped crystals, is extracted. Its savour is acrid and disagreeable, like that of tobacco, and its actions are equally poisonous with that of *atrophine*. The least portion placed on the eye causes a dilatation of the pupil, which remains for a considerable length of time. In a dry state it is not an alkali, but by the addition of water it soon becomes so.

Daturine.

The same chemists, MM. Geiger and Hesse, have extracted this alkali from the *datura stramonium*. It crystallises in the form of small, colourless, and brilliant prisms; it is free from odour; its taste is at first slightly bitter, but afterwards very acrid; it is very poisonous, one eighth of a grain sufficing to kill a sparrow in three hours. It possesses an action over the pupil of the eye similar to that of hyoscyamine.

Table of the number of Vaccinations in France, from 1828 to Jan. 1833.

Years.	Number of Vaccinations.	Number of Departments.
1828	349,143	53
1829	296,132	52
1830	253,972	44
1831	214,360	40
1832	362,834	55

The Influenza in Paris.

For the last ten or twelve days an epidemical complaint has attacked most of the patients in Salpetriere. From the striking resemblance it bears to the influenza which preceded the cholera in 1832, its intensity, the number of persons attacked, and its extension to some individuals in the town and in the department of Seine et Oise (Arpajon, Montlhéri, &c.), it merits the attention of practitioners.

It commenced in Salpetriere among some of the incurable patients in St. Leon Ward, the least healthy division of the establishment. Since that time it has extended through most of the wards, and has in many cases terminated fatally. It commences, in general, by pain in the throat, shivering, and cephalalgia; in slight cases the symptoms subside at the end of three or four days, but sometimes far different is the result; the disease becoming rapidly aggravated, attacking the head, chest, or abdomen, and frequently terminating fatally in twenty-four hours.

The principal appearances observed on making post-mortem examinations in this disease, have exhibited inflammation of the larynx and trachea, more or less acute, and extending in some instances down to the divisions of the bronchial tubes, engorgement of the lungs, red or grey hepatisation, &c. In other cases in which there has been vomiting and constipation, but no pain in the epigastric region, there was redness of the stomach and

intestines, either in patches or along the whole extent of the intestinal tube. In a third class of cases, where the symptoms seemed principally referable to the head, and which were most quickly fatal, injection of the brain was found. The symptoms of affection of these different organs have been in many patients combined; and when such has been the case, the disease has invariably terminated fatally.—*Journal Hebdomadaire.*

Reports of Societies.

WESTMINSTER MEDICAL SOCIETY.

Saturday, April 12th, 1834.

DR. COPLAND in the Chair.

Artichoke and Colchicum in Rheumatism—Ovarian Dropsy.

THE minutes of the preceding evening having been confirmed,

Dr. Epps brought forward a motion on the inexpediency and injustice of granting exclusive privileges to any University not enjoying exclusive advantages.

After some discussion it was determined that the consideration of the question, originating in consequence of certain proceedings which had taken place, during the last week, in the city of London, should be deferred until next Saturday.

Dr. Epps asked if any gentlemen present had tried preparations of artichoke in rheumatism?

Mr. Chinnock had received a letter from the country extolling the anti-rheumatic effects of this medicine, and stating that used in this disease it was never known to fail.

Dr. Addison thought that much doubt was to be entertained of the virtue of any medicine which was stated to be universally successful. In giving colchicum he had lately found a peculiar condition of the heart brought on by its administration, but he had been assured by Dr. Jackson, of America, who was then accompanying him round the wards of the hospital, that such symptoms were always looked for by the American practitioners. If the artichoke possessed the same properties of arresting disease which colchicum did, he thought it would be an invaluable medicine.

Dr. Epps did not think that, in speaking of

the merits of colchicum, sufficient justice was done to Mr. Haydon, the first person who had used it in inflammatory diseases;—in the work on this subject, published by the above-mentioned gentleman, it was stated that this medicine should be given in powder with saline purgatives, and should be continued until stools were produced.

Some further observations on this topic having been made,

Dr. Addison related the following case:—A woman, æt. 40, had suffered for four or five years from ovarian dropsy, when the sac burst and induced peritoneal inflammation and great distress; the abdomen increased in size, but the swelling there was not partial but universal. The inflammatory symptoms were subdued, and after some time it was perceived that the abdomen gradually became less, and seemed to be undergoing the same process which surgeons expect to take place in hydrocele; the tumour can now be traced into the iliac fossa, but much diminished in size. In general, the contents of ovarian dropsy were not of a sufficiently irritating nature to cause inflammation, as in the case mentioned last week by Dr. White. Wounds of the stomach might be recovered from, but if the contents escaped into the abdominal cavity, the accident would in general terminate fatally.

A Member related a case, in which the fluid, to a considerable amount, had escaped into the peritoneal cavity, from an opening in the stomach, without causing any inflammation.

After which the meeting separated.

The following motion was moved, seconded, and carried by the Society, and the subject to which it relates is to be discussed at the next meeting:—

“That the bestowal of a charter upon any university, with power to the medical faculty thereof to confer medical degrees, will be a most injurious manifestation of the exclusive principle, which, by conferring on the lecturers (themselves constituting the medical faculty) an exclusive advantage,—an advantage quite independent of their skill as lecturers,—will prevent not only the exercise of a fair competition between these lecturers and those of other institutions not so favoured, but will also tend, as diminishing this competition, to

injure the university itself, by inducing students to enter thereat, not so much from the excellence of the lectures delivered, but on account of the twofold circumstance that the lectures of such lecturers have adjoined to them the peculiar advantage of qualifying for an examination for a degree, and that the lecturers themselves constitute the medical faculty to examine their own pupils; thus removing so many motives to exertion from the minds of lecturers themselves.”

MEDICAL SOCIETY OF LONDON.

Monday, April 14th, 1834.

W. KINGDON, Esq., President, in the Chair.

Production of Syphilitic Symptoms from the Use of Mercury.

IN continuance of the discussion of last Monday Mr. Kingdon related two cases, tending to prove that mercury would produce in the system symptoms analogous to those caused by syphilitic poison.

Dr. Johnson did not think either of these cases at all conclusive; it was a well established fact, that ulcerations of the throat, such as those which formed the principal feature in the second case, when once established in the system, would appear at intervals of a year, or even less, when no mercury had been given.

Dr. Whiting coincided with Dr. Johnson in his views upon this subject, and expressed his opinion, that the idea of mercury producing in the system symptoms analogous to the venereal disease, was totally erroneous.

Mr. Clifton thought that the exhibition of mercury might produce peculiar states of the constitution, favourable to the development of syphilis, but there was not sufficient evidence to prove that venereal symptoms were ever caused by mercury, for the occurrence of this disease, after the exhibition of mercury, did not prove that the disease arose from its use.

Mr. Dendy referred to two cases in the Medico-Chirurgical Transactions where tubercular eruptions appeared after mercury, and which were in his opinion caused by the mercury; he conceived that this medicine might produce dubious appearances by lying latent in the system, and if applied to crude sores would cause a phagedænic tendency which might be called disease.

Dr. Johnson had had many opportunities of seeing men go into battle with their mouths affected with mercury, and had observed that, when wounded, the sores in such patients healed even more rapidly than in others not so affected.

Mr. Stevens had seen mercury cause various symptoms, but did not conceive that it ever produced disease resembling syphilis.

Mr. Headland said the ambiguous appearances, which mercury caused, would show the ambiguity of the subject ;—he had seen nodes produced after taking three grains of mercury, the periosteum being in the first instance affected.

After some further observations by Mr. Jones and Dr. Johnson the Society separated.

THE LONDON UNIVERSITY HOSPITAL.

A MUSEUM consisting of specimens and preparations of morbid anatomy, midwifery, and various casts, with numerous prints and drawings, has been presented to the London University, for the use of the students of the new North London Hospital, which will be opened at Michaelmas with 110 beds, by Gore Clough, Esq., of Upper Norton-street, Fitzroy-square. The museum cost 3000*l*. This is a noble bequest, and shows a kind feeling to an institution founded on liberal principles.

THE PARLIAMENTARY INQUIRY.

ON Tuesday last Sir David Barry, Sir George Tuthill, Dr. Holland, Dr. Paris, and Dr. Hume were examined. On Wednesday, Dr. Stanger, Dr. Tweedie, and Dr. Copland. On Thursday, Dr. Henderson, Dr. Farre, Sir W. Knighton, Dr. Birkbeck, Dr. James Johnson, and Dr. James Clarke. On Friday Dr. Ramadge is to be examined. Next week, Sir Astley Cooper, Mr. Guthrie, Mr. Brodie, and Mr. Green will be examined.

We are delighted, but very much surprised, at the complete knowledge which Mr. Warburton possesses of all medical abuses. Had he been a member of the profession, nay President of the College of Physicians or Surgeons, he could not be better acquainted with the subject. We feel perfectly convinced that a radical and most beneficial reform will be effected in all the branches of the medical profession ; such as will promote the interests of science, while it protects and secures those of the public. We see no reason why it should not be accomplished this Session of Parliament.

THE
London Medical & Surgical Journal
Saturday, April 19, 1834.

THE MEDICAL PROFESSION IN ENGLAND.

UNDER this imposing title a pamphlet has just issued from the political press, to which, as the first publication in defence of things as they are, we are in justice bound to call our readers' attention,—although, in doing so, we give it a notoriety beyond what it solicits. It is, in truth, intended merely for the members of the legislature, in order to counteract the effect of some observations, made in both Houses, upon the presentation of the petition of the Licentiates. It is undoubtedly the manifesto, of which the appearance was revealed to a confidential contemporary on a late occasion, and repeated on its authority by us. We shall analyse its contents for the satisfaction of the profession.

After prefacing with Lord Durham's speech upon presenting the above petition, the pamphleteer states his object to be to examine the truth of the allegations of that speech, and of an assertion made in the House of Commons, that the science of medicine in this country, as compared with its condition on the Continent, is in a state of the greatest barbarism.

This last assertion is refuted to the satisfaction of dukes, marquises, &c. by the simple fact, that almost all families of distinction, on going abroad, take with them medical men of their own choice, and of their own country !

As to the comparative supply of physicians, in reference to the population of the different capitals, London, Paris, and Berlin, a point which attracted Lord Durham's attention, the pamphleteer argues thus:—

“What is meant by a phy

England is a very different person from him who is so designated on the Continent. For physicians, in the present English acceptance of the term, the demands of the public are not great; but if men are called doctors abroad, who having had the education of apothecaries, are content with the remuneration of apothecaries, their numbers will necessarily be great; but call themselves what they will, they are in fact minor practitioners. Any forcible attempt, on the part of the legislature, to bring about such a change here would probably be impracticable, so long as the country retained the least trace of civilisation and intellectual superiority."

Of course it is unnecessary to expose the utter ignorance displayed in the passage just quoted, of the medical schools in France and Prussia. A writer, who can make such observations, is sure to find an analogy in the present demand of reform in medical education to the supposed conspiracy of the *workies* in America against an aristocracy of knowledge. (p. 7.)

It is impossible to state, within reasonable limits, the precise object of the cursory remarks which occupy the rest of the pamphlet. After stating that the public is not in the slightest degree interested in the denominations of the profession, the next question of importance set forth is—

"How to maintain, in a *high* station, the medical character for the benefit of the public, that they may have persons of *high* abilities, generous and honourable feelings, and of perfect integrity, to whom they may apply for assistance and advice in the most serious distresses of private life. The question for the *educated* and *informed* public is not as to mere qualification for the administration of remedies, but whether they will be honestly and conscientiously administered, and whether

the administrator of them is one who, by his conduct and propriety of behaviour, is fit to be the confidential adviser of a family."

But how is the public to be assured the medical practitioner possesses the requisites of skill and character? By comparison says the pamphleteer, and for the purpose of that comparison there must be created

"A *high* order of well educated medical men, bred up in the honourable feelings of gentlemen, with acquirements which belong to the scientific, the literary, and most polished orders of society."

There is nothing particularly exclusive in all this; and to those who are unacquainted with the style of Sir Henry Hallford, and who cannot detect the undercurrent of his application of the sounding epithets, is there in it any thing peculiarly appropriate to the Fellows of the College of Physicians? But a few pages afterwards the application is pointed in a manner not to be mistaken.

"If the man, who has studied several years in *an* university, and qualified himself with every accomplishment which the best education of *this* country affords, is to be upon the level of a five years' apprenticed apothecary, who has lived behind a shop board, mixed up and dispensed medicines according to the order of his master, attended as many lectures as may enable him to pass an examination, and to be licensed as soon as he has attained the limited age;—why then there will be none but the lower order of practitioners."

We agree with the President in his conclusion;—but we ask, as has been asked elsewhere, does an university degree certify the possession of these rare accomplishments? and to whom, but to one versant in stratagems, whose high moral character can bend to—misrepresentation, when it suits his purpose, does the level-

ling system belong, which is stated with such insinuating address?

As to the plan, that there should be a Board to examine and license all medical men, that is despatched in a few words; it is stated to be "absurd enough. The Board, indeed, to use a homely simile, may furnish joiners and carpenters but will supply no cabinet-makers, nor call into existence any architects, who will understand the difficulty or intricacy of disease, as it affects the complicated machinery of the human frame."

We have almost exhausted our patience in criticising such matter; but we cannot forbear adding a word relative to the distinction of *Fellow* and *Licentiate*. On this subject the positions of the pamphleteer finish his labours. He did well to reserve the climax of absurdity for the close of the pamphlet. The profession, it is stated, has by no means *exact* notions of the distinction, and as to the public, whose good opinion is worth having,—

"It seldom happens that they send for the College list to examine whether the Doctor is a Fellow or a Licentiate. How then does it happen, that in this great metropolis, a large portion of the leading physicians are in the class of Fellows? The answer is ready and obvious. They have almost all of them been brought up at the English Universities, where, in the course of a *liberal* and *classical* education, they have had early opportunities of forming valuable friendships and extensive acquaintances with those destined, in after life, to fill *high* situations in society, with whom they have imbibed the *same* feelings, formed *congenial* habits, made *similar* acquirements in *science* and *literature*, &c. A few are admitted into the Fellowship by other modes of election;—and with what feelings does the College regard such a preference? Surely none of

envy or of jealousy. They choose a man already eminent in his profession; and, by this preference and distinction, do not think they make him a more dangerous rival; but conceive that they only add *to the respectability of their own body, at the same time that they pay him a compliment.*"

We hope we have afforded our readers some amusement from the tone and temper of the extracts we have made from the President's defence. The conventional language of *high life*, which pervades the pamphlet, is in admirable keeping with the utter indifference it displays to the necessities of society at large,—of the people; and the assumption of peculiar refinement, as distinguished from manly bearing, is more than paralleled by the effrontery of the claims it asserts for the little coterie it defends to superior medical attainments.

THE UNIVERSITIES.

The spirited and enlightened conduct of the Cambridge petitioners has, as was to be expected, produced a reaction upon the little elements of bigotry; and we understand an effort is to be made to present a University petition to a reformed Parliament, in favour of intolerance.

"When the sun shines, flies think of coming forth."

We hope the representative of the medical faculty at the Caput will, by the exercise of his veto, save a learned body from such a disgrace*. Matters are come to that crisis, that the legislature must interfere. The ebullition of party spleen cannot counteract the course of justice, and may provoke animosities and jealousies which it would be difficult to allay.

* We have since heard Dr. Hewett has acted with becoming spirit. There can be no corporation petition.

The London University has received a liberal accession to its museum; and what is of still greater importance to its interests, the City has resolved to support its petition for a charter of incorporation. To the extent of degrees in literature and science we are its hearty well-wishers; but, we must again protest against any grant of the power of conferring medical degrees to it, or to any particular school of medicine. We shall return to this subject if we see occasion.

From a pamphlet we have just received from Edinburgh*, it seems the rival parties of Professors and Private Teachers at that city carry on their war of invective with much spirit, but to very little use. Our northern brethren require to be informed, that a Committee is actually sitting in London, which will unquestionably take into its cognisance their mutual complaints.

THE PARLIAMENTARY COMMITTEE.

It is announced by the very highest authority, that the "Fellows" of the College of Physicians have been *roused into increased excitement* during the progress of the Parliamentary Inquiry. This singular advertisement must undoubtedly induce a large flow of visitors to the Committee Room, under the expectation of seeing some interesting specimens of corporation irritability when the fit is on; and, sooth to say, it is possible the curious may be entertained or grieved with many an exhibition of irritated self-interest, of bigotry convulsed,—the consequence, we presume, of increased excitement,—of, in short, the desperate struggle of dying monopoly; and, according to their tempers, they may despise or pity the wretched

exposure of assurance and inconsistency, into which a false position leads persons reputed honourable, and justly respected in their private relations. The *morality*,—to use an expression now notorious for its abuse,—the morality of corporations or societies is very distinct from the morality of individuals. Conscience the former have none, other than the most exclusive self-interest; and responsibility is so subdivided, that his share sits lightly upon each member.

But what shall be said of the imputation the same authority has ventured to throw upon the honourable Chairman of the Committee?—That he has lent himself to the malice of certain exclusives! We know nothing of associations—we are averse to coteries of all descriptions—we know nothing of the business, but that we have exclusive confidence in the integrity and honour of Mr. Warburton, and the rest of the Committee. But is it not truly ridiculous to hear complaints about the quality of witnesses called, when it is palpable every possible interest has its representative in the Committee, who may call whom he pleases. There is no pleasing some people, beat high, or beat low. Something analogous to this takes place in other operations beside flogging. Some of the persons whose assistance was needed have been called. —What then?

Reviews.

Traité des Maladies des Enfants nouveau-nés, et à la Mamelle, fondé sur de nouvelles Observations Cliniques, et d'Anatomie Pathologique, faites à l'Hôpital des Enfants-Trouvés de Paris, dans le service de M. Baron. Par C. M. Billard, D. M. P., Membre de Plusieurs Sociétés Savantes. Deuxième Edition, augmentée d'un Mémoire Médico-Légal sur la Viabilité du Fœtus; avec des Notes, et une Notice sur

* Refutations of Some Misstatements respecting the University of Edinburgh. 1834.

la Vie et les Ouvrages de l'Auteur, par M. Ollivier (D'Angers). Paris et Lond., 1833. 8vo. pp, 728. J. B. Baillière.

A Treatise on the Diseases of New-born Infants and those at the Breast, founded on Clinical Observations and on Pathological Anatomy, made at the Foundling Hospital at Paris. By C. M. BILLARD, M.D., &c. Second Edition. Enlarged by a Medico-Legal Memoir on the Viability of the Fœtus, with Notes, and a Notice of the Life and Works of the Author. By M. OLLIVIER (D'Angers).

THIS work differs from those which have preceded it, in being based on pathological anatomy, and proves its author to have been possessed of indefatigable industry. Before we institute a comparison between it and extant productions on the same subject, we shall inform our readers of its contents and of its merits. It consists of two parts, arranged as follows:—Part I. contains six chapters, with introductory remarks, entitled “Study of the General Phenomena which the exterior Examination of the Infant presents.” Chapter I. Attitudes of the Infant; II. Coloration of the Integuments; III. Fall of the Umbilical Cord; IV. Exfoliation of the Epidermis; V. Of the Size of the Infant and its Weight; VI. On the Means of Expression of the Infant: art. 1. Of the Cry, considered in relation to Semeiology: art. 11. Expression of the Physiognomy; VII. Of the State of the Pulse in Infants; VIII. Of the Feebleness at Birth. Part II. contains seventeen chapters—“History of Particular Diseases.” I. Of the Diseases of the Skin; II. Of the Diseases of the Digestive Apparatus; III. Of the Diseases dependent on the Intestinal Canal; IV. On the Diseases of the Urinary Apparatus; V. On Peritonitis; VI. On Ascites; VII. On Hernia of the Abdomen; VIII. On Diseases of the Respiratory Apparatus; IX. On Diseases of the Circulatory Apparatus; X. On Diseases of the Cerebro-Spinal Apparatus; XI. On the Diseases of Locomotion; XII. On Diseases of the Organs of Generation; XIII. On Diseases of the Lymphatic System; XIV. On Diseases of the Eye; XV. On the Jaundice of New-born Infants; XVI. On the Accidental Tissues of New-born Infants; XVII. Alteration of the Blood. The Medico-Legal Dissertation on the Viability of the Fœtus, considered in relation

to the Pathology of the new-born Infant, concludes the work.

We are bound to add our testimony in favour of the admirable execution of this work so far as it extends; but we cannot agree with some of our contemporaries, that it exceeds every other on the subject. We are not, however, surprised at their declarations, because it is manifest to us they are unacquainted with those works which are far more comprehensive and useful. Of all the reviews of this work which we have perused from the pens of our contemporaries, that of the Glasgow Medical Journal is the fairest and best. It clearly demonstrates the insufficiency of M. Billard's work. In this production the Physical Education or Management of Infants is entirely omitted; though treated of, we admit, very imperfectly, by Underwood, Dewees, Hamilton, and Burns. So far as this most important subject is concerned, the works of Capuron, Underwood, Dewees, and Robertson, are infinitely superior to M. Billard's. But our worthy contemporaries overlook this part of infantile medicine; they reason but to err. They seem to be ignorant of the importance of the physical management of infants, upon which depends the proper development of mind and body, of the health, happiness, and misery of man. They forget that millions of human beings are annually, we think we might almost say daily, destroyed by bad management, by errors in clothing, by imprudent exposure to the vicissitudes of the weather, by bad air, filth, and every form of mismanagement. They overlook the immense mortality of infants from this cause: amounting to one-half in some countries, two-thirds in others, four-fifths where physical education is the best; and yet they pronounce a work which is silent on the proper rearing of infants superior to those which describe it.

But M. Billard's production is founded on pathological anatomy, abounds with a vast number of observations or inspections illustrating diseases of the digestive, respiratory, circulatory, and all the physiological systems, and therefore it is unequalled. Those who have jumped at this conclusion must be ignorant that M. Capuron has arranged the diseases of infants in this manner; and, moreover, by giving an eloquent and unequalled account of their physical education, has produced decidedly the most comprehensive and

useful work on the physical management and diseases of infants. Dr. Dewees approaches him, Dr. Underwood's production is more remote, the works of Dr. Hamilton and Dr. Burns are epitomes, that of Mr. Robertson better than either on physical education, to which, with the mortality of children, it is not confined; but every one of these authors has produced an imperfect work; and, in truth, there is not a complete treatise on infantile hygiene and medicine in our language. It could not be expected that such a work was likely to be published, when our Colleges of Physicians and Surgeons in this United Kingdom, the Dublin College of Surgeons excepted, exclude midwifery and diseases of women and children from the examinations for medical qualifications. It would be foolish to suppose or expect, that students will attend to the physical management of infants, or their diseases, when they are not to be examined on such subjects; and hence we find a universal ignorance among practitioners upon this branch of medicine—hence the lamentable ignorance of parents, who have no guides but ignorant men to direct them in the rearing of infants and the prevention of their diseases. Under all these circumstances, it is no wonder so few have studied the physical education and diseases of infants, and that our best works should be defective.

But, readverting to the treatise which elicited these strictures, we are ready to acknowledge that, so far as it goes, it is extremely valuable, and the result of faithful and accurate observations.

The revered and zealous author illustrates the diseases of which he treats, by several dissections of each class; and these he repeats to an unnecessary extent on many occasions. It was unnecessary to detail three, four, or six illustrations of the same disease in the same tissue or organ, and by this plan augment the size of his book. Some of our readers will, no doubt, think this a great advantage. M. Billard is entitled to great merit for having adduced so many histories of each disease, and added the morbid appearances. In this he is, as far as our researches enable us to judge, unrivalled; and his work will be one of reference and authority; but it does not supersede in utility for study and practice, those which we have already mentioned. It appears to us

that there is something more than a knowledge of pathological anatomy requisite, for the inculcation of correct precepts on the physical education of infants, on infantile hygiene, and on the judicious treatment of the diseases of children.

Lectures on the Morbid Anatomy, Nature, and Treatment of Acute and Chronic Diseases, delivered in the Theatre of Anatomy, Webb-street. By the late JOHN ARMSTRONG, M.D., &c. Edited by JOSEPH RIX, M.R.C.S. 8vo. pp. 851. London, 1834. Baldwin and Cradock.

Few physicians of the present century attained such high and well-merited celebrity as the late Dr. Armstrong, nor made such a deep impression on his brethren by his numerous works. His fame was raised to the highest pitch in Sunderland by his Treatises on Typhus, Scarlet, and Puerperal Fevers, which made a great number of converts to his opinions. On settling in London, the author of standard works of that date found himself rejected for incompetence by the College of Physicians! This body, among whom Jenner and Hooper were not worthy it seems of being admitted as Fellows, had previously refused its licence to Mason Good, and for these and many similar misdeeds is now arraigned by the profession before the Medical Committee of the House of Commons. But the insult to Dr. Armstrong was soon avenged by a liberal and enlightened profession, who espoused his cause, employed him in every direction, and ensured him in a few months a larger practice than that of any of his opponents. It is worthy of remark, that some of his examiners at the College went so far as to state, to non-professional persons, that they considered he was not the author of his own works. But all opposition proved useless; he was ultimately admitted a Licentiate of the College, and recognised as a lecturer on the practice of medicine, by the most powerful of all our medical corporations, the Company of Apothecaries. He speedily became the most popular lecturer of the day, and left every one of the Fellows far behind him. We have now a literal copy of his last course of Lectures on the Practice of Medicine before us, and can declare with truth, it is very far superior to any hitherto delivered, or published, by the elect

of Pall Mall East. We can conscientiously recommend it to the notice of the medical world, for it well deserves high commendation. It bears internal evidence of extensive experience and great judgment. It will be found a valuable acquisition to the profession, and we should strongly recommend students to possess themselves of it. The work is arranged by a man of sound sense, great practical experience, and a very extensive knowledge of the subject,—one who possessed, in no ordinary degree, the invaluable power of communicating the truths of science in a clear, simple, precise yet popular manner, without the slightest garnish of technology, and scarcely with the introduction of a word which is not intelligible to the humblest understanding. But however highly we estimate this production, it is not of a description which we can illustrate by extracts.

French Hospital Reports.

HÔPITAL DE LA CHARITÉ.

Sanguineous Tumour in the Hand.

In the month of March, 1830, a man, *ætat.* 57, was admitted into La Charité for a sanguineous tumour, of the size of a pullet's egg, situated at the tip of the little finger of the right hand; it was covered with plastic lymph, but the integuments were deficient over the part; it felt firm, but the slightest touch caused it to bleed freely. The man complained of lancinating pain, which was so violent that it disturbed his repose. There was enlargement of one of the glands in the corresponding axilla. The first appearance of the disease, which was dated thirty years back, was a small black line below the nail of the little finger. This line remained in an indolent state for the space of twenty-eight years, that is to say, until two years previous to his admission into the hospital. At the commencement of these two years, the line began to swell, and became painful; the nail came away, and from beneath a sanguineous tumour, at first flat, then globular, sprouted forth; during the three months previous to his applying for advice, it had acquired double the volume which it had previously. M. Boyer, who recognised the disease as a specimen of true fungus hæmatodes, disarticulated the finger at the middle phalanx. In fifteen days the patient was discharged

cured, and has not since had any return of the complaint. The dissection of this tumour showed a black coloured firm substance, formed by the interlacing of an infinity of capillary vessels in a varicose state; it was observed that it did not adhere either to the bone or periosteum, these two being perfectly healthy.

HÔTEL DIEU.

Similar Case.

A young man, *ætat.* 18, presented himself for admission at the Hôtel Dieu during the month of October last, in consequence of a tumour situated in the palm of the right hand. It was of the volume of a small hen's egg, flattened, indolent, soft to the touch, apparently without pulsation, and occupying the base of the metacarpal bone of the thumb. M. Dupuytren, judging from its analogy with one which he removed twenty-five years before, considered the disease to be of a lipomatous character, and determined upon its removal. An incision two inches long having been made over the tumour, the bistoury penetrated into a pouch filled with spongy tissue; a considerable deal of hæmorrhage now took place, but this was restrained by applying a small piece of sponge, and then with the aid of a pair of forceps, the tumour was dissected from its adhesions. It appeared to consist entirely of spongy tissue with numerous veins and arteries in a state of dilatation. Repeated hæmorrhages took place from the wound, but compression finally succeeded in arresting these, and a cure, much delayed by the formation of pus in different parts of the fore-arm, was effected in two months.

Tertian Fever.

A printer upon calico, 38 years of age, was admitted on the 29th of March for the above complaint. His residence is at Jouy, situated in a damp, marshy valley, where intermittent fevers abound. He was in the hospital last autumn for a similar attack of fever, but was discharged perfectly cured, and has remained well until ten days previous to his present admission, when he was so much affected by finding one of his comrades unexpectedly dead in his bed, that, the same night, his body became covered with urticaria. On the following day at noon he had a perfect paroxysm of intermittent fever, which lasted nearly four

hours; and from this time the paroxysms returned at regular intervals of two days.

M. Chomel stated to his class, that this was a case of essential intermittent fever, appearing to be independent of all organic lesions, and was one of the cases in which the preparation of quinine acted with marvellous efficacy. A blister with ammoniacal ointment was placed upon the epigastrium; as soon as the skin was raised this was removed, and two grains of sulphate of quinine were applied to the sore. The result of this case has not yet been published.

Foreign Body in the Oesophagus.

A female advanced in years, sans teeth, swallowed a piece of meat, which passed into the oesophagus, and there stopped. M. Pujos found the old lady, a quarter of an hour after the accident, nearly suffocated, breathing with great difficulty, and unable to swallow even the smallest quantity of fluid. Attempts were made with the probang to assist the passage of the obnoxious body, which was situated at the lower part of the neck, but without success. Having tried what art would do, without relief, the case was left to nature, and at the end of twenty hours the food fell into the stomach, the place for which it was originally destined. —*Gazette des Hopitaux.*

Extirpation of a Tumour in the Axilla—Torsion of the Arteries—Cure.

BY M. BÉRIOL DE VILLIERS, NIEVRE.

Beauchef, ætat. 34, had been troubled for more than a year with a large scirrhus tumour in the left axilla. It had existed for some years, but about twelve months since it had attained the size of a walnut, and became painful. On the 3rd of February, 1834, the tumour was carefully dissected out. During the operation a branch of the thoracica long was divided, but ceased to bleed as soon as torsion was applied; two other large arteries were cut and twisted successfully. No hæmorrhage occurred, and seven weeks after the operation the patient was discharged cured.

British Hospital Reports.

WESTMINSTER HOSPITAL.

Hare-Lip and Cleft Palate.

A FINE boy, of interesting appearance, about six years of age, was brought to the hospital on March 29th, in order to be operated on by Mr. White for hare-lip. In addition to the hare-lip, there was also a broad fissure extending entirely along the soft and bony palate. When the child was only a month old he was unsuccessfully operated on by Mr. Alcock. No further steps were taken from that time up to the present, the health of the boy being generally good. Much inconvenience, however, resulted from the deformity, and his enunciation

was completely unintelligible, except to those constantly in the habit of being near him.

The surgeons of the hospital consulted on the subject, and Mr. Guthrie gave it as his opinion, that something more might be done than merely operating for hare-lip, and mentioned the operation, staphy corrapihid, which he once performed successfully on a young lady, 17 years of age. The operation consisted in passing ligatures through the soft palate, freshening the edges and bringing them together. Mr. White said he had never seen the operation performed, and wished to transfer the operation to Mr. Guthrie for the succeeding Saturday, April 5th.

Previous to the arrival of the child, Mr. Guthrie explained the nature of the operation which he was about to perform. He exhibited a small curved needle, armed with a ligature, the eye end of which needle was placed between two blades of an instrument, called the porte-aiguille, and secured by a movable slide. The needle was to be passed through one side of the soft palate, and held by a pair of dressing forceps, the slide then being drawn back, the needle can be drawn through, and being again fixed in porte-aiguille, the same operation is to be performed on the other side; two ligatures generally require to be passed; the edges of the soft palate are to be removed with a bistoury or pair of scissors; the ligatures are then to be tied and cut short. The patient is to be kept on exceedingly low diet until the ligatures have separated; during the operation the patient is to be held as steady as possible, otherwise the instrument may pierce the pharynx or elsewhere.

When the child was introduced, the ligatures were applied with great trouble; the boy bore this part of the operation with great fortitude, but afterwards became so very much agitated and alarmed, that it was found advisable to remove the ligatures, and the operation was postponed to some future period, when, it is hoped, the patient will be better able to appreciate the immense advantages which in all probability would result from the performance of this novel but ingenious operation.

The feasibility of the operation has been clearly proved by the instance quoted by Mr. Guthrie. Thus it is sufficiently evident, that it is merely necessary that the patient should have arrived at that time of life, when he sees the necessity of submitting patiently to the knife of the operator, in order to render this a very useful operation.

ST. GEORGE'S HOSPITAL.

Vascular Tumour of the Lip.

Thomas Heffenden, æt. 20, was admitted into Ratcliffe Ward, originally, we believe, under the care of Mr. Babington, but was afterwards transferred to the care of Mr. Brodie. His countenance is very much deformed from there being an extensive puffy swelling of the

whole of the upper lip and of the right side of the face. The inner surface of the lip is completely lifted up and coated, the swelling and enlargement extending on the right side over the antrum to a line even with the lower eyelid, where the cuticle covering it is hard and indurated to the touch, and he very naturally complains of a great deal of pain in the cheek.

The history which he gives of this somewhat singular case is this:—He says that, as well as he can recollect, there has always been some degree of swelling there; that it therefore began when he was a child, and he remembers that it increased much after receiving a blow on the lip from falling against the sharp edge of a chair. When it first attracted his attention it was soft and pulpy in consistence, and of the size of a horse-bean, and always gave him pain up to within the period of the last month. He once had some leeches applied to it, and it was cut open, but no good result followed from this, and it has continued steadily and gradually to increase up to the present time. At present the oral extremity of the lip is two inches thick, and there is a corresponding swelling, but not of the same thickness, up the whole cheek. There is no unusual pulsation or heat of skin to be felt on the surface, but the tumour is evidently vascular in its nature, and the capillary vessels of the part are highly injected with blood. Gradual and steady pressure empties the tumour of blood, and the lip then appears flaccid, but the moment this is removed it refills, and becomes again as large as ever.

6th. Mr. Brodie punctured the tumour in several places with a needle, and a large quantity of blood flowed from it. He complains of a great deal of pain in the cheek, which is rather inflamed. Pulse quick and hard; tongue yellow and furred.

R. Lotio spirit. parte affect. applicand.

*H*austus sennæ cras primo mane sumend.

9th. An abscess which had been previously projecting over the region of the right antrum burst to-day internally, on the inside of the cheek, and discharged a large quantity of matter, which he says has relieved him very greatly, and the swelling of the cheek has in consequence partly subsided.

R. Hydrarg. submur. gr. iv.

*P*ulv. antimonial. gr. v., statim sumend.

R. *H*aust. salinæ, ʒ iss. vin. antim.

*T*act. *℥* xx. sextis horis capiend.

12th. There is a very free discharge from the abscess; he complains of much bodily weakness; the pulse is rather quick and sharp; the tongue clean and the bowels open.

He thus continued to progress for some time, there being very little done for him either one way or the other; indeed, we almost doubted whether Mr. Brodie intended to do anything for him until towards the beginning of March, when several punctures were made into the texture of the lip, and a

large quantity of blood was lost, but apparently without any effect in diminishing the size of the lip, although each operation appeared to cost the man considerable pain.

March 14th. The effect of the last puncture has been to cause the man considerable swelling of the whole lip and right side of the face. Pulse quick and full; tongue furred; skin hot and feverish. Ordered to be kept in bed and to take the saline draught of the hospital every six hours.

Mr. Brodie remarked, that he had a case somewhat similar to this (though situated in a different part of the body—the eyelid) at present under his care; it was of course impossible to puncture it, and he was passing setons through it with the best effect; the parts were agglutinating and solidifying together very favourably.

16th. The tumour, though not much diminished in size, is evidently less vascular; and the patient's general features wear a more pallid appearance, from the loss of blood which he has sustained at different times by the punctures; his general state of health is better, and the attack of fever, under which he was labouring at our last report, has subsided. He complains very bitterly of the pain, which affects the globe and surrounding parts of the right eye, after each operation of puncturing the tumour, and begged very hard to be allowed to leave the hospital, adding that he would rather bear with the inconvenience of the tumour, than be put to such horrid torture. Mr. Brodie pointed out to him that the pain of which he complained so greatly, arose from the abscess in the cheek, and not from the vascular tumour in the lip*; and that he had much better remain in the hospital, and let every remedy be tried for him that could be, and further remarked, that it was very uncertain whether his case could be cured or not.

Mr. Brodie requested that the other surgeons would see the case and give him their opinion upon it, but this the patient prevented, for finding that nothing very beneficial could be done for him, he left the hospital.

APOTHECARIES' HALL.

NAMES of gentlemen to each of whom the Court of Examiners granted Certificates of Qualification on Thursday, April 10th.

William Bell	Pocklington.
Johnstone Vicars	Exeter.
Edwin Skeate	Bath.
William Blaxland	Lynstead.

* This could scarcely have been the truth, as the pain, if caused by the abscess, must have been constant, whereas the patient only complained of it after each puncture was made in the lip; the pain was most probably caused by injury done to some of the nervous filaments supplying the upper lip, communicating with those that go to the lower eyelid.—R&P.

BOOKS.

Pathological and Surgical Observations on Diseases of the Joints. By C. BRODIE, V.P., R.S., Serjeant-Surgeon to the King, and Surgeon to St. George's Hospital. Third Edit., with alterations and additions. 8vo. pp. 334. London: 1834. Longman and Co.

The Signs, Disorders, and Management of Pregnancy; the Treatment to be adopted during and after Confinement; and the Management and Disorders of Children. Written expressly for the use of Females. By DOUGLAS FOX, M.R.C.S., and one of the Surgeons of the Derbyshire General Infirmary. 8vo. pp. 207. Derby: 1834. Mozley and Sons.

CORRESPONDENTS.

A Dublin Subscriber.—We were well aware of the great interest which would be excited

by a public course of lectures on embryology, delivered by Professor Montgomery, of Trinity College, and by his illustrations from the largest and best selected obstetric museum in the United Kingdom. We accordingly requested them to be taken down, and shall publish them every fortnight. We expect them in a few days.

Galen.—We have heard of the fracas between Professors Elliotson and Green, and the intended appeal to the Medico-Chirurgical Society; but as they are both Arcadians, we shall leave them to fight their own battles

The London University Charter.—The corporation of London would be the last in Europe to advocate monopoly; and had it been aware that the charter which it petitioned for, would confer the exclusive privilege of lecturing on the University, to the injury, or most likely the destruction of all the medical schools in the metropolis, it would never have lent itself to solicit such a manifest injustice. We prophecy that no school in London will obtain the power of granting medical degrees, but a faculty will be established for that purpose. This body ought to consist of a certain number of eminent physicians and surgeons, not lecturers, and of lecturers on the different branches of medical science, chosen by ballot from all in London, so that the candidates for examination could not know the examiners, and the business of teaching would not be interfered with. It would be preposterous to have an examining faculty composed of individuals who are not conversant with the actual state of the different sciences, which few, if any, actually engaged in practice are.

Medicus.—The Parliamentary Inquiry has brought to light every abuse in the College of Physicians, and in the Hospitals in the metropolis. There is now no doubt in our mind but the medical polity of the United Kingdom will be arranged *de novo*.

LECTURES

ON THE

PRINCIPLES, PRACTICE, & OPERATIONS OF SURGERY,

BY PROFESSOR SAMUEL COOPER.

*Delivered at the University of London,
Session 1832—1833.*

LECTURE LXXXVI., DELIVERED APRIL 12, 1833.

GENTLEMEN,—I have next to bring under your consideration *Scrofulous Inflammation of the Conjunctiva*. The symptoms characterising it are *slight redness, great intolerance of light, and pimples, or small pustules* on the conjunctiva. It seldom attacks infants at the breast, but children at some period between weaning and the eighth year. At the commencement of the disease, the redness of the conjunctiva is very slight and in patches, or clusters of vessels; but, afterwards, it increases, and becomes more uniform, and the sclerotica appears to participate in the inflammation. At the apex of each of the clusters of blood-vessels, one or more minute pustules arise; sometimes a single elevated point, of an opaque white colour, near the centre of the cornea; and sometimes numerous pustules, scattered over different parts of the conjunctiva. In some cases they are small, and filled with a thin colourless fluid, when they are termed *phlyctenulae*; in others they are larger, and contain fluid more like pus. It is not known, whether there is any specific difference between the phlyctenular and the pustular cases; but it has been observed by Mr. M'Kenzie, of Glasgow, that the pustular cases are in general attended with less intolerance of light.

The phlyctenulae and pustules may be absorbed, and then, if situated on the cornea, they leave behind a white opaque speck—the effect of that effusion of lymph, which surrounds every circumscribed abscess, but which in time generally disappears. Sometimes, however, a vascular speck is left, which is more difficult of removal.

Quite as frequently these pimples burst, and are converted into ulcers, sometimes superficial and considerable in extent, more

commonly deep, and funnel-shaped, as you see in this engraving, so beautifully coloured by the hand of Beer himself. If they happen to penetrate the cornea, the aqueous humour is discharged, and a small piece of the iris protrudes, and unites to the sides of the aperture, which is closed by an opaque indelible cicatrix partially or entirely obstructing vision; but the cicatrix from a superficial ulcer may leave no permanent opacity.

The *excessive intolerance of light*, attending scrofulous ophthalmia, is one of the most distressing symptoms. The child is quite unable to open the eyes in ordinary daylight; and every attempt to look up instantaneously brings on a strong spasmodic contraction of the eyelids. The pain from the light is most severe in the morning; for, in the afternoon, the intolerance of it is sometimes so far lessened, that the eye can be opened. Notwithstanding the violent suffering produced by light, there is frequently an insignificant degree of redness, and the cornea often remains perfectly transparent, or with merely one minute opaque speck upon it, and a few red vessels running over the sclerotica.

The intolerance of light is always attended with *epiphora*, a gush of tears following every attempt to open the eye. Hence the eyelids and cheeks are sometimes much excoriated and swelled.

Occasionally, the disease is conjoined with iritis, but more frequently with ophthalmia tarsi, and other scrofulous complaints.

In the *treatment* of scrofulous inflammation of the conjunctiva, there is not so much occasion for powerful antiphlogistic remedies as in some other inflammations of the eye. In the first stage, which is short, you may apply a few leeches, followed by blisters behind the ears, or on the nape of the neck. The secretions of the skin and alimentary canal are to be restored, for which purpose you may prescribe the liq. ammon. acetatis, combined with the vinum antimonii, and a small quantity of the syrup of poppies. Or you may give rhubarb and carbonate of soda, in equal parts, with or without a little of the hydr. c. creta. For the ulcerations on the cornea, the solution of nitrate of silver is the best application. I scarcely need

say that the eye should be protected from the light with a green shade, or by darkening the room. If the cornea be opaque, calomel, or the blue pill, should be given, so as slightly to affect the system.

After the first inflammatory stage is over, tonics are generally found beneficial, especially the sulphate of quinine, with a light nutritious diet.

The best applications to the eye itself are slightly astringent lotions, used tepid, as the decoction of poppyheads, with a small quantity of spirit of wine in it; or a weak solution of the acetate of ammonia, or a solution of one grain of the oxymuriate of mercury in eight ounces of distilled water. In France, the collyria for scrofulous affections of the eye frequently consist of a weak solution of iodine in distilled water, with a small quantity of hydriodate of potash.

Let me next speak of *inflammation of the external proper tunics*, which is characterised by a great deal of external redness, pain, and intolerance of light, soon followed by increased lachrymal discharge and febrile disturbance. The redness begins on the front of the globe, immediately round the cornea, where it forms a red zone, to which numerous vessels proceed from the back of the eyeball. In inflammation of the conjunctiva, the redness begins at the circumference of the organ, its anterior part being at first free from it, and the sclerotica retaining its natural white appearance: the discharge is also of a mucous or puriform kind.

The redness is quite different in the two cases: in inflammation of the sclerotic coat, the vessels seen through the conjunctiva exhibit a pink colour, or a lively carmine appearance, which forms a striking contrast to the bright scarlet tint of the vessels in conjunctival inflammation. The vessels of the sclerotica always follow the motion of the eye; while those of the conjunctiva are capable of being moved, independently of the eyeball. The distended vessels of the inflamed sclerotica run in straight lines forwards to the edge of the cornea, but those of the inflamed conjunctiva have no such distribution, as they are reticulated. However, the conjunctiva soon participates in the inflammation of the external proper coats, and the cornea looks dull. The eye feels dry and stiff, with a burning or aching pain, and feeling of tension, pressure, or as if sand were lodged in the eye. As the disorder increases the pain grows more severe, and extends to the back of the head and nearest temple. Intolerance of light is a strongly-marked symptom of inflammation of the sclerotica, another feature in which it particularly differs from conjunctival inflammation.

Although the eye may be at first dry and stiff, the lachrymal secretion is soon restored, and even increased, so that whenever the eye is opened there is a considerable effusion of tears. In unfavourable examples, attended with chemosis, the cornea first turns grayish, then white and cloudy, and lastly yellow, as if

pus were deposited in its texture. The yellow matter, however, is not fluid; neither does it make its way to the surface like pus; but the cornea ulcerates, and the deposited matter is removed by ulceration. A similar deposition may take place in the anterior chamber, producing what is termed *hypopyum*. When the whole cornea is thus affected, the ulceration may penetrate the anterior chamber at several points, the aqueous humour escape, and the iris either protrude or become adherent to the inflamed cornea.

The degree of danger will depend on the state of the cornea: when this is only slightly affected there is no danger; when chemosis is present, and the cornea is gray, or white; or when a yellow deposition takes place in its texture, followed by ulceration, and escape of the aqueous humour, sight will be impaired, and perhaps totally lost.

Before speaking of the treatment, I may as well describe

Inflammation of the entire Eyeball; or Ophthalmitis, for the practice in each of these cases is founded on the same principles. Common inflammation, seated both in the external and internal structures of the eye, when fully developed, is characterised by considerable pain, increased external redness, more or less swelling of the organ; at first dryness of the eye, but afterwards augmented secretion from the lachrymal gland; and redness and swelling of the upper eyelid. The pain is not confined to the fore-part of the eye, but is deep-seated, and extends to the eyebrow, cheek, temple, and back of the head. At first, the redness is inconsiderable, and chiefly in the vessels of the sclerotic coat; but the conjunctiva very quickly participates in the inflammation, and the distention of its vessels produces the bright scarlet colour, which conceals the fainter pink or carmine tint of the sclerotica. The conjunctiva then begins to swell, and a deposition of coagulable lymph takes place, not only in the texture of the membrane, but in the loose cellular tissue which unites it to the sclerotica. You know, gentlemen, that this red circular projection of the conjunctiva round the cornea, giving the latter membrane a sunk appearance, and even materially concealing it, receives the name of *chemosis*.

Light is very offensive, so that the pupil contracts to exclude it, and the eyelids are spasmodically closed. In a more advanced stage, the colour of the iris is altered, its brilliancy disappears, and its usual motions in different degrees of light are interrupted; the pupil diminishing and losing its clear black colour. The cornea becomes more or less opaque, and vision is lost, sometimes from this cause, and the closure of the pupil; sometimes from injury of the retina, as when the sight is destroyed, though the cornea and pupil do not completely obstruct the light; and frequently from all these circumstances together. Sometimes the thickened eyelids protrude, an *ectropium* of the lower one taking place, and a

portion of the conjunctiva projecting in the form of a piece of red flesh.

So violent an affection of a vascular and sensible organ, situated in the immediate vicinity of the brain, necessarily produces a great deal of sympathetic inflammatory fever. If the disorder be not checked, suppuration of the eye occurs, preceded by severe throbbing and rigors, and no relief is experienced till the cornea bursts, and the matter is discharged, the vitreous humour and crystalline lens usually passing out at the same time. The eye then shrinks into the orbit; its form is completely destroyed, and its functions annihilated. When the disease does not proceed quite so far, the patient escapes, perhaps, with opacity of the cornea, a closure of the pupil, or injury of the retina. With respect to the prognosis, if chemosis be formed, the cornea cloudy, the colour of the iris changed, and the pupil contracted, the eyesight is in considerable danger.

The causes of inflammation of the proper coats of the eye may be wounds; the irritation of extraneous substances lodged under the eyelids; exposure of the eye to a draught of cold air; immoderate exertion of the organ, particularly in the examination of minute shining objects, and in hard study by candlelight; and certain states of the atmosphere. As predisposing circumstances, I may mention a full habit, or plethora, a disordered state of the digestive organs, intemperance, and costiveness.

Treatment of Inflammation of the External Proper Coats of the Eye, and of Ophthalmitis, or General Inflammation of the Eyeball.—

1. The first indication is to remove, if possible, the cause, as, for example, extraneous substances. The eye should be examined in a good light; and, if nothing be discovered on it, the lower eyelid should be depressed, and the inferior portion of the globe brought into view by the patient looking upwards. If no particle of extraneous substance can be detected in this way, the patient should turn the eyeball downwards, and the upper eyelid be raised, so that the upper portion of the globe may be seen. In most cases, the extraneous body lodges in the concavity of the upper eyelid, which must then be everted. The eyelashes are first to be taken hold of, and the eyelid drawn downwards; and, while steady pressure is made against its upper part, by placing a probe across it, its ciliary margin is to be carried upwards and backwards.

When small particles of metal stick in the cornea, they should be removed with the point of a cataract-needle.

Next to the removal of the exciting cause, bleeding is the chief means of subduing these forms of ophthalmic inflammation. Venesection is to be practised, and from twenty to forty ounces should be drawn; and, after two or three hours, if the pain return, you should take away from twelve to fifteen ounces more without delay. The blood may also be taken from the temple, or nape of the neck, by cupping, or from the temporal arteries. Be sure

also, gentlemen, to protect the eye with a green shade, and to have the room darkened.

Neither must you omit the repeated application of leeches, which are to be put on the temple, eyebrow, or just below the inner angle. You must also prescribe purgatives, with saline antimonial medicines; and, after depletion, have recourse to blisters.

With respect to topical applications, if the case be attended with violent headach, the decoction of poppyheads may be used as a fomentation. In other instances you may bathe the eye, by means of an eye-cup, with tepid water, or with a warm collyrium, containing five grains of the sulphate of zinc, or acetate of lead, dissolved in four or six ounces of rose-water. In proportion as the irritability of the eye lessens, the application may be used colder.

When the acute stage has completely subsided, you may introduce between the eye and eyelids, once or twice a-day, two or three drops of the vinous tincture of opium; but, as long as much tenderness and aversion to light continue, its use must be deferred, and depletion repeated.

The proposal of puncturing the anterior chamber, and letting out the aqueous humour, when the case is attended with a sense of distention and a cloudiness of the cornea, may be said to be renounced at the present day.

Instead of this practice, when there is risk of effusion, or opacity, I usually give calomel and opium, and keep open a blister. Two grains of calomel, with half a grain of opium, four times a-day, may be administered until the mouth becomes sore.

For the cure of any remains of chronic inflammation, I may say, that astringent applications, blisters, the occasional use of leeches, and the free exposure of the eye to the open air and daylight, are generally the right measures.

Gentlemen, I will now speak of *Scleritis*.

—There are two very remarkable forms of inflammation of the eye, most frequently arising in adults from atmospheric influences, viz.—the *catarrhal* and the *rheumatic*. The *catarrhal*, as you know, is an affection of the conjunctiva; the *rheumatic*, of the albuginea and sclerotica, occasionally extending to the iris. In the *catarrhal*, the red vessels give a reticular appearance; in the *rheumatic*, they are radiated, or in the form of a zone, and seated under the conjunctiva. *Catarrhal* ophthalmia is an inflammation of a mucous membrane, and attended with an increased secretion from it; *rheumatic* ophthalmia attacks the fibrous membranes of the eye, and is not accompanied by any morbid secretion from its surface. The pain in catarrhal ophthalmia, is like that of sand under the eyelid, does not extend to the head, and is felt chiefly in the morning, or when the eyes begin to be moved. The pain in rheumatic ophthalmia is throbbing and deep-seated, not in the eye chiefly, but round the orbit, and is severely aggravated from sunset

to sunrise. In catarrhal ophthalmy there is little intolerance of light, in scleritis a great deal.

Rheumatic inflammation is by no means a good name for the complaint, as it is not connected with a rheumatic constitution; it is a primary affection, and not the result of any transfer of rheumatism from other parts to the eye. *Scleritis* is certainly a better term. At all events, this inflammation only resembles rheumatism in its exciting causes, its accompanying pain, its exacerbations, and its treatment.

In scleritis, the fasciculi of distended vessels advance in radii towards the edge of the cornea, and sometimes even a little beyond it. They are of a bright red colour, and the degree of inflammation in the conjunctiva itself is never such as to conceal them. In general there is no tendency to chemosis, nor do the eyelids take part in the disease, but there is a haziness of the cornea and pupil, attended with a slightly contracted state of the latter opening, and a sluggishness in the movements of the iris.

The iris may even become slightly discoloured, and lymph be effused from it; but a severe degree of iritis seldom attends rheumatic scleritis. Suppuration and ulceration also seldom or never follow this affection of the eye; but there is a considerable degree of symptomatic fever, increasing with the nocturnal paroxysms of pain. The digestive organs are deranged, the bowels confined, and the excretions morbid.

Treatment.—Blood is to be taken from the arm, and leeches afterwards applied to the forehead and temples. Calomel and opium are effectual in lessening the severe pain in and around the orbit. Two grains of calomel and one of opium may be given every evening till the gums are affected, when the calomel may be omitted, and ten grains of the compound powder of ipecacuanha administered in lieu of it.

The forehead and temple may be rubbed with a mixture of olive oil and extract of opium, or with warm laudanum; and in chronic cases, with equal parts of laudanum and tincture of cantharides.

Blisters are likewise to be put behind the ear, or on the temple, or nape of the neck.

I believe, gentlemen, that in rheumatic scleritis the iris should be kept moderately under the influence of belladonna, either by smearing the moistened extract upon the eyebrow and eyelids every evening at bed time, or by infusing ʒj. of the extract in each ounce of the laudanum used for rubbing the head. I may also inform you, that mild purgatives and the warm foot-bath at night, with sudorifics, will be found eminently useful.

In chronic cases you may give small doses of sulphate of quinine; and, in old mismanaged ones, eight or ten drops of the liquor arsenicalis, three times a-day, will give great relief.

Local applications have little effect. The lunar caustic solution, which is almost a specific for catarrhal ophthalmy, is decidedly injurious in rheumatic scleritis; but, when all painful and febrile symptoms are gone, and little more than chronic redness and weakness of the eye remain, the vinum opii may be dropped once or twice a-day into the eye.

Catarrho-rheumatic ophthalmia affects both the conjunctiva and the sclerica. The feeling of roughness, or sand, between the eyelids and eyeball, and the secretion of a puriform fluid, indicate the participation of the conjunctiva in the disorder, while the nocturnal accession of racking pain in and around the orbit marks the affection of the sclerica. In this case chemosis is by no means uncommon, and the eyelids generally adhere together in the morning from the thickened state of the Meibomian secretion. There is also considerable intolerance of light, with epiphora.

The conjunctival pain, which is compared to the feeling produced by sand between the eyelids and eyeball, is felt principally in the morning, or when the eyelids are moved. The sclerotic pain is nocturnal. The conjunctival pain is referred to the surface of the eye, and sometimes to the forehead. The sclerotic pain is felt deeply throughout the orbit.

The cornea frequently ulcerates, or pus is effused between its layers, constituting what is termed *onyx*. The latter, when arising from catarrho-rheumatic ophthalmy, is a very serious effect. It generally commences at the lower edge of the cornea, in the shape of the white spot at the root of the finger-nails, and sometimes extends so as to cover one-half of the cornea. The pus in it is rarely absorbed. The cornea at length ulcerates over the centre of the onyx, and the pus is discharged, but the ulceration frequently makes its way into the anterior chamber, the aqueous humour escapes, and the iris protrudes.

There is also commonly, just before this state of things, an effusion of lymph in the pupil; the iris changes in colour, and the pupil is often obliterated.

The pulse is generally quick and sharp, the tongue white, and the nocturnal pain prevents sleep.

Causes.—Amongst the poor the catarrho-rheumatic ophthalmy may generally be traced to exposure to cold nocturnal air, deficient clothing, and want of proper shelter. North-easterly winds promote its occurrence. It is much more frequent in old than young or middle-aged persons.

Treatment.—1st. Venesection—from ten to thirty ounces, and repeated.

2nd. Leeches to the temple.

3rd. Scarifications are sometimes advised when there is chemosis, but it is a practice which I do not follow.

4th. Calomel and opium every night.

5th. Opiate frictions about an hour before the expected attack of pain in the orbit.

6th. Pupil to be kept dilated with belladonna.

- 7th. Blisters behind the ear.
- 8th. Purgatives; a brisk dose of calomel and jalap at first, and afterwards mild laxatives.
- 9th. Sudorifics; liq. ammon. acet., warm diluent drinks, and the pediluvium.
- 10th. In the chronic stage, the sulphate of quinine and mineral acids.
- 11th. Local applications; the solution of two to four grains of the nitrate of silver in an ounce of distilled water, dropped upon the conjunctiva once a-day, relieves the painful feeling of sand, and speedily removes the other symptoms of conjunctivitis.

The eye is to be bathed three or four times a-day with a tepid solution of the oxymuriate of mercury, one grain to eight ounces of distilled water.

The edges of the eyelids are to be smeared with the ung. hydr. nitratis, weakened. If onyx take place, it is not to be punctured, as such practice is always followed by protrusion of the iris and opacity.

Scrofulous corneitis is a slow disease, occupying weeks and months, and sometimes years. The conjunctival covering of the cornea, and substance immediately under it, are chiefly affected. The redness of the sclerotica is not considerable, the vessels are minute, and arranged in a zone round the cornea. Not unfrequently there is a reddish ring at the circumference of the cornea, with red vessels extending to the centre of this membrane. In some cases the conjunctival covering is thickened, and reddened so as to look like a piece of red cloth, whence the term *pannus*. The cornea is more or less opaque and rough; sometimes only hazy, sometimes marked with white streaks or specks, sometimes uniformly white. Occasionally its convexity is increased; the pupil is not unfrequently dilated, with a tendency to amaurosis; there is not much intolerance of light, a striking contrast of this form of scrofulous inflammation of the eye to what is noticed in the pustular variety. In a few cases, however, the patient cannot endure the light, and there is epiphora. The pain is not very severe, and the complaint soon becomes chronic, especially after the cornea has become opaque. Gentlemen, you will also usually notice that the pulse is quick, the patient restless at night, and the skin harsh and dry. The disease is most common in subjects about puberty, and often accompanied by symptoms of struma.

Treatment.—Leeches are to be applied and repeated, but not so as to weaken the patient. You may also try small doses of tartarised antimony, and then the sulphate of quinine, and Dover's powder at bed-time. Calomel combined with opium, so as to affect the mouth, after the acute symptoms have ceased, has great effect in clearing the cornea. Colchicum, sarsaparilla, and elm bark, are useful as alteratives in scrofulous corneitis, but not generally deemed equal to sulphate of quinine.

The local applications are fomentations

with poppy decoction, and the steam of hot water, with a little laudanum in it. Employ also blisters. The best *stimulating* applications, after all acute inflammation is over, are the vinum opii, a collyrium of the nitrate of silver, or a weak solution of iodine in distilled water, according to Lugol's formula, explained to you in a former lecture. When there is any tendency to iritis, the pupil is to be kept dilated with belladonna. When the cornea is very convex, denoting an unusual accumulation of aqueous humour, the discharge of this fluid is sometimes recommended, but rarely adopted.

LECTURES ON THE THEORY AND PRACTICE OF MEDICINE,

BY WILLIAM STOKES, M.D.,

Delivered at the Medical School, Park Street, Dublin.—Session 1833–34.

LECTURE XVIII.

Treatment of Chronic Hepatitis—Neuralgia of Liver succeeding to Hepatitis—Connection of Hepatic with Gastro-Intestinal Disease—Modes of Transmission of Disease from the Mucous Surface to the Liver—Phlebitis of the Vena Porta—Obstruction of the Porta—Collateral Circulation—Occurrence of Inordinate Appetite—Singular case of Pulmonary, Hepatic, and Intestinal Fistula—Hepatic Neuralgia.

GENTLEMEN,—We come now to the consideration of the treatment of chronic hepatitis. It is of great importance in a case of this kind to place your patient under such circumstances as will ensure the full and favourable action of the remedies employed. The use of wine, spirits, and all kinds of exciting food must be laid aside; the patient must not use any thing capable of producing fever during the process of digestion. So long as any kind of food or drink produces uneasiness and sensations of heat and fulness, you may be sure that it will do more harm than good. Give him what will support his strength without exciting the vascular or nervous systems during the process of digestion.

You must next prevail on your patient to give up the use of active purgatives by the mouth. This is a point which you should strongly and firmly insist upon, as in consequence of the ordinary costive state of the bowels which accompanies chronic inflammation of the liver, the patient is generally in the habit of having recourse to those temporary and hurtful remedies. It is the same thing in cases of chronic hepatitis as it is in chronic gastritis, you will find the subjects of these diseases taking different purgatives every day. Break your patient of this practice if possible; you will have some difficulty in doing so, for he has been long habituated to it, and you must exercise all your authority in putting a stop to the pernicious habit. Instead of pur-

gatives by the mouth, make him use every day an emollient injection. You may, if necessary, give occasionally mild laxatives by the mouth, as Rochelle salts, manna, castor-oil, or something equally mild, and in this way you will be able to secure a regular alvine discharge once in the twenty-four hours at least. But where there is considerable pain and tenderness in the region of the liver, this plan alone will not be sufficient; you must apply relays of leeches, a practice which has a most admirable effect in chronic hepatitis. I would advise you to apply cupping-glasses over the leech bites; by doing this you get as much blood as you wish, and you will generally save your patient from the annoyance of an oozing hæmorrhage. When piles exist, it will be often useful to apply leeches to the anus, followed by the hip-bath. But I have no hesitation in saying, that as a general mode of relieving hepatic disease, the application of leeches to the right hypochondrium is far preferable in every point of view. You may in the next place have recourse to blisters, and I have frequently employed blisters, alternately with leeches, with the best results. Tartar emetic ointment, in the form which I have already mentioned, croton oil frictions, and other modes of counter-irritation, will assist materially in bringing about a successful termination. But these must be continued long, and used over an extensive surface.

In this way, by regulating your patient's diet, keeping his bowels open by enemata, or the mildest laxatives, by small and repeated local bleedings, with counter-irritation, you will frequently succeed in removing all the symptoms of chronic hepatitis without the use of mercury. But if, after having carefully employed all these measures, the symptoms manifest a degree of persistence, if your patient has not already taken a large quantity of mercury (which is not likely to be the case in this country), and if he be not of a scrofulous habit, I see no reason why you should not have recourse to mild doses of mercury. For this purpose nothing answers better than to prescribe, once or twice a-day, a pill composed of hydrarg. c. creta, blue pill, or a small quantity of calomel, combined with rhubarb, extract of hyosciamus, and taraxacum. It will be seldom necessary to bring on actual salivation, but if the pain continues to be severe, the swelling undiminished, the symptoms obstinate, and no contra-indication existing, you may bring him under the influence of mercury, and keep him so for a short time. The best mode of doing this is to direct him to rub in a drachm of the camphorated mercurial ointment every day; and if you have employed blisters, you can assist the frictions by dressing the blistered surface with mercurial ointment.

Some practitioners are in the habit of substituting the nitro-muriatic acid for the mercurial treatment, and there appears to be evidence that it is an advantageous mode of

practice in these cases. The best mode of using this remedy seems to be the endermic; and hence bathing the feet, or sponging the right hypochondrium with the acid, are most recommended in chronic affections of the liver. As it is convenient to have a formula for making the nitro-muriatic solution, I shall give you the following. Take of strong nitric and muriatic acids of each four ounces, and add to these eight ounces of pure water. Here you have a sixteen-ounce mixture; of this combination you may take from two to five ounces, and mix them with three gallons of warm water. This, I believe, is the form recommended by Mr. Amesy. Having placed this solution in a foot-bath, or tub, you should direct your patient to keep his feet in it for twenty minutes or half an hour. If the bath be of proper strength it will communicate to the skin a pricking sensation, if not, you may increase its strength by adding an ounce or two more of your mixture. The same solution will answer for sponging over the liver.

There is no doubt, that in certain cases of chronic hepatitis this remedy has been found decidedly useful, and as its employment is unattended with any dangerous or disagreeable consequences, it has strong claims to our notice. The cases of chronic hepatitis to which it seems to be peculiarly adapted, are first, those where mercury has been used irregularly, or for a long time without any benefit, and secondly, where the patient is of a broken-down constitution, and where you are anxious to dispense with the use of mercury if possible. Here the intromuriatic treatment is of decided value. I need scarcely remark to you that this acid frequently acts upon the system somewhat like mercury, producing tenderness of the gums and ptialism. Such an effect as this furnishes us with an example of these cases, in which we find other remedies as well as mercury producing a decided effect on the salivary glands, and exercising a very powerful influence over hepatic and syphilitic affections. An interesting fact bearing on this point is related by Mr. Cox, in his account of his residence on the Columbia river. Several of his party who used a strong decoction of the fresh sarsaparilla were salivated.

There is one circumstance connected with the treatment of chronic hepatitis, which I believe has not been sufficiently dwelt on. You may have a case in which there was distinct evidence of chronic inflammation, and where, under the influence of judicious treatment, the signs of inflammation and organic derangement subsided, but where severe pain still continues to be felt in the region of the liver. The nature of this pain is often mistaken; it is supposed to depend upon a continuance of inflammation, while it is in reality nothing more than a mere neuralgic affection—a remnant or successor of the former disease, to which the antiphlogistic treatment is totally inapplicable. Under such circumstances the patient goes from one practitioner to another,

taking different medicines, and submitting to repetitions of the usual modes of treatment, but with little or no benefit. Now I have seen in several cases, this symptom yield completely to treatment calculated to remove purely neuralgic affections. In a case lately under my care of a gentleman who had been attacked with enteritis and hepatitis in India, and who had taken enormous doses of calomel "for the liver," and of croton-oil "for the bowels," this circumstance occurred. When first I saw him he was emaciated, the skin yellow, the urine high-coloured, with thirst, costive bowels, and great tumefaction in the region of the liver. These symptoms completely subsided under treatment, but a violent pain, running at intervals, continued obstinate. This was rapidly removed by a course of the carbonate of iron, and the use of the belladonna plaster.

It is of great importance in the treatment of chronic hepatitis, to bear in mind the state of the gastro-intestinal mucous membrane. You are aware that the disciples of Broussais are of opinion that almost all cases of hepatic inflammation are secondary to a gastro-enteritis; that the first morbid action is on the surface of the intestinal tube, and that it is transmitted from this to the liver. I have taken a considerable share of pains in investigating this subject, and have examined very carefully the question as to the complication of hepatic inflammation with disease of the gastro-intestinal surface, and the conclusions to which I have come are the following:—In the first place, that most cases, whether of acute or chronic inflammation of the liver, present the complication, more or less, with disease of the intestinal mucous surface, and that in the majority of instances there is some degree of actual disease of the digestive tube. It would appear also from observation of different cases of hepatitis, that in a great many the affection of the liver has been secondary, and that symptoms of disease of the digestive tube have preceded those of hepatic irritation. But on the other hand we must admit that the hepatic affection may be primary; that the liver has the irritative, and that disease has been subsequently propagated to the gastro-intestinal mucous surface. Lastly, we may have hepatitis both acute and chronic, quite independent of any disease of the mucous coat of the stomach and bowels. This, I believe, is the rarest case: still it does occur. You observe, therefore, that the doctrine of the physiological school, that all hepatic inflammations are secondary to a gastro-enteritis, is not supported by the authority of facts. It is therefore wrong to say that every case of acute or chronic hepatitis is preceded by gastro-intestinal inflammation. Facts have been brought forward to show that not only has inflammation of the liver been observed in the simple state, and independent of any complication with intestinal disease, but that the affection of the liver has distinctly preceded the symptoms of gastro-enteric disease. On

the other hand, however, I am free to admit that these are the exceptions rather than the rule, and that in the majority of cases hepatitis is either secondary or complicated with disease of the gastro-intestinal surface.

Now a very interesting question comes to be considered, and this is, how does the disease come from the gastro-intestinal surface to the liver? Pathology informs us that irritation may be transmitted from one organ to another in three different modes. First, sympathetically, as through the medium of the nerves. Thus, long continued stimulation of the stomach is reflected upon the liver, the liver sympathises with the suffering organ in its vicinity, and finally becomes diseased itself. It is in this way that many chronic affections of the liver and stomach terminate in affections of the neighbouring viscera and dropsy. The first mode then, in which disease may come to affect the liver from the gastro-intestinal surface, is by sympathetic irritation. The next mode is supposed to be the actual transmission of disease along the biliary duct from the duodenum to the liver. Inflammation commences in the duodenum, this creeps along the ducts until it reaches the liver, which takes on the inflammatory action in its turn. Several persons of high authority have supported this view of the question, and assert that they can actually demonstrate the passage of inflammation along the ducts. Without denying the possibility of this, yet I feel convinced that it is rare. I have never been able to discover this mode of propagation of inflammation from the duodenum to the liver; and it must be remembered that in the great majority of cases of duodenitis we cannot detect inflammation in the liver or its appendages. The last mode by which disease may be transmitted, is the propagation of inflammation along the course of the veins belonging to the portal system, that is to say, there is phlebitis of the portal system, and the inflammation travels along the veins until it arrives at and attacks the liver. That this has occurred is proved. But we may suppose that in certain cases, disease of the liver may result from a phlebitis of the minute mesenteric veins, without a continuous spread of inflammation to the larger trunks: just as the lung is affected in cases of phlebitis of the extremities, not by actual spread of inflammation, but rather, as Mr. Arnott has shown, by the transmission of the products of that inflammation.

Inflammation of the portal veins is a circumstance which possesses great interest in a pathological and practical point of view; it is a curious process, and there are some singularities connected with it which have a claim on our attention. In the Clinique Medicale of Andral, there is a case given of a patient who, after labouring for some time under symptoms of fever and gastro-enteritis, was attacked with pain and tension in the region of the liver, followed by jaundice. On dissection, marks of inflammation were found in the stomach and

ileum, there was also some disease in the colon, and the liver was found to be enlarged and presenting the ordinary marks of inflammatory action. On a more minute examination, nearly all the mesenteric veins and the trunk of the porta were discovered to be in a state of intense inflammation, while, on the other hand, the lining membrane of the vena cava was found to be in its normal and healthy condition. Here we have a very remarkable coincidence between disease of the liver and of the portal system. First, the patient had fever with gastro-enteric inflammation, and then pain and tension in the region of the liver, followed by jaundice. On dissection the mesenteric veins and the trunk of the porta are found inflamed, this condition extends to the liver, the substance of which is found tumefied, red, and friable. I believe there can be no doubt that disease of the liver may be brought on by disease of the abdominal veins, particularly those of the portal system. It is a very curious fact, that with symptoms, such as many practitioners would not hesitate to call chronic hepatitis, we may have phlebitis, terminating in obliteration of the porta and even of the vena cava. In such cases nature generally makes an effort to keep up the venous circulation; in consequence of the obliteration of the internal abdominal veins, the external ones become enlarged, and produce a supplementary circulation to a certain extent, and in this way life is prolonged. This drawing, which represents the appearance of a patient labouring under this form of disease, will give you some idea of the matter. You observe the patient's belly is enlarged and prominent, his extremities cedematous, and here you see those enormous veins passing along the surface of the belly, and keeping up a collateral venous circulation. In the patient, from whom this drawing was taken, the porta and cava were obliterated. These are the epigastric and other superficial abdominal veins which ascend to anastomose with the thoracic, intercostal, and axillary veins.

I shall now relate, as briefly as possible, the particulars of this very remarkable case. The patient, who was the subject of it, laboured for more than twelve months under jaundice, accompanied by wasting of flesh and prostration of strength, but for the first eight months he had not been confined to bed. He suffered, however, very considerably even at this period from constant pain in the epigastrium and swelling of his feet. Now, in this country, we would be very apt, under such circumstances, to say that he was labouring under chronic hepatitis. At the end of the eight months he became bed-ridden, and the large veins, which you here see, began to make their appearance. Although he was wasting in flesh, still he had a canine appetite, and was always complaining that he had not enough to eat. This is an interesting fact. It has been observed in other cases, and tends to throw some light on the share the mesenteric and other abdominal veins

have in the process of absorption. In *tabes mesenterica* it has been often remarked, that the little patients have generally enormous appetites, and as it would appear from the same cause, a deficiency of nutritious absorption, with this difference merely, that in the disease before us it is the veins that are diseased, whereas in *tabes mesenterica* it is supposed to be the lymphatics. But to return to our case,—this patient had, as I remarked, a very voracious appetite, by indulging which he brought on repeated attacks of constipation and colic. He then got diarrhoea and dropsy, for which he was tapped twice without any benefit. From observing that there was in this case an extraordinary supplemental circulation, leading to the inference that there was obstruction of the deep-seated veins; from remembering that the appearance of the patient, and the more prominent symptoms coincided with those of a former case, in which obliteration of the porta had been discovered after death; from these circumstances, and the remarkable voracious appetite, M. Reynaud, under whose care the patient was, came to the diagnosis of phlebitis of the portal system, extending to and affecting the liver; and this diagnosis was subsequently confirmed by dissection. He was, however, unable before death to explain one symptom which was present, namely, infiltration of the lower extremities. You are aware that when the general venous circulation is obstructed either in the chest or belly, we have anasarca of the lower extremities, but when the obstruction affects only the portal system, then we have ascites as the first phenomenon. If you had two cases of dropsical effusion, in one of which there was, *first*, œdema of the lower extremities, in the other *first* ascites, you could thus determine where the primary obstruction existed. M. Reynaud was at a loss to account for this symptom in the present case, as he had not observed it before in the other case, and as the swelling of the feet had preceded that of the belly. On dissection, it was found that the right branch of the porta had been obliterated by the growth of a yellow substance, somewhat like the middle coat of arteries; the same was found to exist in the corresponding hepatic veins, and the inferior cava was found obliterated to the distance of three inches from the left auricle. The left branch of the porta was pervious, the corresponding hepatic veins much enlarged, and the superficial epigastric veins inoculated freely with the intercostal and axillary veins.

The vena azygos was very much dilated; and, what is extremely curious, a large vein was seen to arise from the union of the sub-peritoneal branches on the convex surface of the liver; this passed through the diaphragm, and emptied itself into the cava close to its termination. Here we have an entirely new vein. It was also observed, that the sub-diaphragmatic veins were much increased in size, and apparently varicose; these passed through the diaphragm, and inoculated with

the pericardial and superficial thoracic veins. Some of them ran up and opened into the great coronary vein of the heart, which was as large as the crural vein. The remaining peculiarities of this curious case were inflammation of the duodenum and gall-bladder. The cavity of the latter was half filled with purulent fluid.

I am fully convinced that I have seen instances of this disease, although I was not so fortunate as to have an opportunity of verifying the diagnosis by dissection. I have seen patients who had wasting of flesh, pain and tension in the region of the liver, and jaundice with this singularly varicose state of the external abdominal veins; some of them had ascites; and I recollect distinctly, that in one case the appetite was very great, and the patient had a tendency to diarrhoea. I am satisfied that in such cases you would be fully justified in making the diagnosis of obstruction of the portal system; and if, in addition, there was infiltration of the lower extremities, there would be a probability that the disease had extended to the cava itself.

Before I proceed to the consideration of a subject to which I have already alluded,—hepatic neuralgia, it may not be amiss to exhibit some specimens of organic lesions of the liver. Here is an example of abscess of the liver:—you perceive the softened yellow degeneration of the substance of the organ; and here is the cavity of the abscess, in which you may observe a loose slough suspended. This portion which surrounds the abscess may be looked upon as a fair specimen of the yellow softening of the liver, before its substance breaks down into a purulent mass. Here is another specimen exhibiting the same phenomena. Here is a very curious example of hepatic abscess, which perforated the diaphragm, and made its way into the substance of the lung. I regret that the whole of this preparation has not been preserved. The rest of the preparations before me illustrate chronic disease of the liver. Here is an example of the disease which has been called cancer of the liver. Time will not permit me to enter into a detail of the pathological circumstances of this case. The patient was a female, who had cancer of the breast, scirrhus of the pylorus, and aneurism of the aorta, with this disease disseminated through the substance of the liver. Here is another preparation of what would be called by many persons pure cancer;—the patient, a female, had cancer of the mamma. This, and the preparation on the other side, exhibiting a mass of white, firm, semi-cartilaginous substances, are examples of what has been called tubercle of the liver. Here is an example of the disease which has been termed whiskey liver, a disease which is said to be ordinarily found in persons who indulge in the use of ardent spirits. This, however, is a term which has been often abused and misapplied; for persons indulging in the use of whiskey may have every form of disease of the liver, and the appearance before you may be detected in

the livers of persons of the most temperate habits. On the label of this preparation is written—"A Specimen of Whiskey Liver," but this you will not mind. There is a very remarkable fact, however, respecting this kind of liver, verified by Professor Carswell, namely;—that this condition of the liver is always accompanied with more or less ascites. I may add, that I have never met with this disease without ascites.

I remember a most remarkable case of disease of the liver, which occurred during my stay in Edinburgh. My lamented friend and instructor, the late Dr. William Cullen, whose loss to pathological medicine was irreparable, and whose splendid attainments and high character justly and rapidly raised him to an elevated rank in his profession, brought me to see a patient. One of the most curious circumstances connected with this case was, that when the patient sat up in bed, a fluid of a serous character was poured out in considerable quantity from the anus; but while he remained in the horizontal posture this did not occur. The patient died shortly afterwards; and on dissection it was found that he had a gangrenous abscess of the right lung, communicating with the pleural cavity, which contained a quantity of a sero-purulent fluid; and a mass of hydatids, some broken down, others perfect and entire. On continuing the dissection, it was found that the cavity of the pleura communicated with the right lobe of the liver through the diaphragm. In the right lobe of the liver the same kind of sero-purulent fluid and a quantity of hydatids were discovered; and, what was still more extraordinary, the cavity in the liver was found to communicate with the colon by a distinct opening. There was then in this very remarkable case a direct communication between the bronchial tubes and the colon, through the pleura and liver. We can thus see that when the patient assumed the erect position, the fluid would immediately pour into the colon.

As I am anxious to finish the subject of hepatic disease to-day, I shall now draw your attention to one of the last points connected with this subject, namely,—neuralgia of the liver. It is a singular fact that a patient may labour under severe and harassing pain in the region of the liver; that this pain may last for months and years; that he may die of some other affection; and that, on examination after death, we may find the liver without the slightest trace of disorganisation; and also, that the organs in its vicinity present no appearance of any organic disease. Many cases of this kind have been observed; and it is the opinion of the best pathologists that they are examples of neuralgia, the seat of pain being the hepatic plexus. It is a disease of no very unusual occurrence, and is often found in females of a nervous and hysteric habit. It is constantly mistaken for hepatitis, and there is no greater mistake than this, or one which is likely to entail more

misery on the patient. The persons who are subject to this affection are, as I remarked before, generally of a nervous and hysteric habit; they complain of pain in the right side of more or less constant occurrence, and this pain, during its exacerbations, is often most excruciating. Now, this circumstance furnishes us with a sort of key to diagnosis; for with this dreadful pain, and, in some cases, exquisite tenderness in the region of the liver, we have the skin cool, the pulse tranquil, no fever, no permanent derangement of the bowels, no tumefaction of the liver. If this were the pain of acute inflammatory disease, a fatal result would be produced; or if it belonged to a chronic affection, it would terminate in organic derangement; and yet we find it existing with a clear colour of the skin and eye, healthy feces, calm pulse, and absence of swelling in the region of the liver. Add to this, that the disease may have lasted for a considerable time, and that it occurs in a person of hysteric and nervous habit. Moreover, if the patient has been treated for hepatitis unsuccessfully, you may make up your mind to the diagnosis of hepatic neuralgia. Here is the diagnosis:—pain in the region of the liver, with occasional violent exacerbations, and accompanied by tenderness of the integuments, but without swelling, symptoms of fever, or abdominal derangement; the disease being of long standing in a person of nervous habit, and having resisted bleeding, mercury, and even counter-irritation, or being made worse by those measures.

Now, gentlemen, it is no uncommon thing to see this disease mistaken for acute hepatitis; and I need not tell you how ruinous to the patient's health such an error must be. When you are in practice, you will meet instances of females labouring under this affection, who have gone through a variety of treatment. When you recollect that the disease occurs generally in hysteric females, and that such persons are injured by depletion, you can conceive how much mischief may be done by repeated bleedings and courses of mercury. Some of the most deplorable cases I have witnessed were those in which neuralgia of the liver had been mistaken for hepatic inflammation by a number of practitioners, and the patient subjected to such modes of treatment as gave her constitution a shock from which it never recovered.

The treatment of this disease must be both general and local, but by no means what you would call antiphlogistic. You will have some difficulty in preventing the patient from getting herself blooded; for though the lancet is inadmissible, yet its employment gives a temporary relief, and this encourages the patient to have recourse to it again. What I would advise you to do in this disease is, first to pay attention to the general condition of the patient. You must pursue a general anti-hysteric plan of treatment, remove every source of irritation and excitement, and take measures

to improve the general health by exercising regimen, moral management, and the judicious employment of tonic medicines. With respect to the pain, one of the most powerful means of arresting and removing it appears to be the use of the carbonate of iron in full doses; and this is an interesting circumstance when we recollect the power which it possesses in removing pain in other nervous diseases. I would advise you to try this after having premised the use of purgatives, and continue it for some time, for you will often find that it will not only cure the pain, but also improve your patient's strength and appetite. While you are giving it, order your patient to take some mild purgative, as compound rhubarb pill, to prevent constipation. When you are about to prescribe a course of carbonate of iron, you should prepare your patient to find the stools coloured. I have known this circumstance taken hold of and turned to their own advantage by quacks. The patient is told that his complaints arise from the existence of morbid and dark coloured matters in his bowels. Preparations of iron are given, and the black matter begins to come away, greatly to the credit of the empiric. After a time the medicine is omitted, and some purgative substituted; the stools become natural, and the trick is complete. During the paroxysms of pain, a mustard plaster, or anodyne stupes and anodyne enemata, will give relief; and in the intervals I would advise you to use the belladonna plaster, after the following formula:—Take of extract of belladonna three parts, of gum ammoniac and soap plaster each one part; spread these on a piece of leather with an adhesive margin, and make the patient wear it over the region of the liver. If there be any tenderness over the lower dorsal vertebrae you may apply a few leeches, followed by narcotic stupes, or counter-irritation.

I have seen this hepatic neuralgia without any hysteric complication. I remember the case of a lady who had three or four healthy children, and had never been subject to hysteria. This lady came up to Dublin to be treated for liver disease—in fact, to be salivated; but happening to fall into the hands of a judicious friend of mine, who recognised the true nature of her complaint, she was treated with carbonate of iron, and cured effectually. I knew another case of a young gentleman, in whom (after being treated for symptoms of chronic hepatitis) this pain continued for a considerable time, and was at length removed by carbonate of iron and the use of the belladonna plaster.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES
OF INFANTS AND CHILDREN,

BY DR. RYAN,

At the Westminster Dispensary, 1833.

LECTURE XVII.

Organisation of Infants at Birth—Progress after Birth—Functions at Birth, and their changes during Infancy and Childhood—Dentition—Etiology, or causes of Diseases.

GENTLEMEN,—At our last meeting I described the symptomatology or diagnosis of infantile diseases, and shall now direct your attention to a general view of the organisation at birth, and its progress afterwards to the functions and their changes during infancy and childhood, in order that you may better understand the etiology or causes of diseases at this period of life.

Every age is characterised by a peculiarity of structure, functions, and diseases; and this position is proved by our inspection of the structure, and our examination of the functions, from the period of nativity to the last hour of human existence.

I have already informed you of the structure and functions of the ovum, embryo, and fœtus; and have now to request your attention to those of the infant at birth and during infancy. I regret to state, that this interesting subject has been too little noticed, both by writers and lecturers. I hold it to be a manifest proposition, that unless we duly appreciate the peculiar structure and functions of our species at birth, we cannot form a just estimate of their peculiar derangements, or of their treatment.

All well educated members of the profession are fully aware, that the human body undergoes different stages of development, from the period of its formation to the cessation of its existence; and hence we observe that physiologists describe ovology, embryology, infancy, childhood, adolescence, manhood, and senescence.

Structure and Functions of the Infant at Birth.—The infant at birth has all its parts distinctly though imperfectly developed; it breathes, and becomes an independent being; it is from seventeen to twenty-two inches in length, and weighs from six to eight pounds, avoirdupois, but sometimes as much as twelve pounds.

After respiration is established it is totally independent of the parent, and is separated from her; it now circulates and purifies its own blood, and requires aliment for its nutrition.

The skin is red, sensitive, and irritable; the muscles are pale, or of a rose colour, soft,

feeble, and powerless; the bones are soft, spongy, vascular, cartilaginous, or membranous, incomplete in many parts, and unable to support the weight of the body; and hence liable to various kinds of distortions, rickets, &c. The brain is soft, highly vascular, and easily lacerated; its relative bulk is very great; the spinal marrow and nerves are proportionally large; and hence infancy is the age of nervous energy, of vivid sensations, and all parts possess great sensibility to painful impressions. The organs of sense are developed; their nerves are very large, but are not as yet accustomed to perform their functions; and hence the senses of vision, audition, &c., are less acute than at a later period of life.

The abdomen and head are very large, the pelvis very small, and the inferior extremities are less developed than the superior. The particular disposition of the lips, that of the palate, and the obliquity of the posterior nares, offer a very favourable arrangement for the mechanism of suction. The stomach and alimentary canal are very much developed; the latter containing a dark fluid (meconium); the absorbent glands, especially in the mesentery, are very large, for the ready conveyance of chyle into the circulation, which is so necessary for the nutrition and growth of all the organs in the body.

The lungs are condensed, of a reddish-brown colour, extremely vascular, and suddenly augment their size and weight after respiration, when they become rosaceous, soft, vesicular, and crepitant. The heart is large, especially the ventricles and arteries, but the auricles and veins are less developed. The remains of the apparatus for the fœtal circulation the foramen ovale, the ductus arteriosus, ductus venosus, and the umbilical vein and arteries persist. The liver is very large, the gall-bladder very small, and containing a reddish bile. The system of the vena portæ, and the spleen, are less pronounced, the epiploon or omentum is thin, and almost deprived of fat. The salivary glands and pancreas are large, because they are so essential to digestion. The kidneys are large, and perform their function more actively than in the adult, as appears by the rapid secretion and expulsion of urine—an excretion so much influenced by slow or rapid digestion.

The bladder is moderately developed, elongated, and so elevated as to be outside the pelvis, and the urachus is attached to it. The larynx is extremely small, and no preparation is made in the nasal fossæ, or mouth, for the articulation of sound. The genital organs and mammae are distinct and small; but the clitoris, nymphæ, and penis, are often very much developed.

The progress of the development of the body from birth to puberty, and the modification of the functions, are very remarkable. The head diminishes in size, the pelvis and lower extremities develop in proportion to

other parts; the remains of the umbilical cord form an indestructible cicatrix; the universal softness of all tissues sensibly and rapidly diminishes; the whole body grows and acquires strength; the function of digestion continues to be performed with energy; the excrementitious part of the food is rapidly passed into the intestines, and is more frequently expelled than at a more advanced age. There are two or three alvine evacuations daily; the motions are fluid, and of a light orange colour; when these are of any other colour, they are depraved and unnatural—the infant is indisposed.

The action of the heart and arteries is much greater in infants than in adults, for the purpose of circulating blood most vigorously to every part for its development. The pulse of a new-born infant is from 120 to 140 beats in a minute; that of the adult from 68 to 72.

Dr. Dawson describes the pulse of infants at the following ages:—at birth, 140; towards the first year, 124; towards the second year, 110; towards the third and fourth, 96; when the milk-teeth fall out, 86; at puberty, 80; at manhood, 75; at sixty, 60.—(*Practice of Physic.*)

M. Biliard gives the following account of forty-one healthful infants, from one to ten days old:—in eighteen the pulse was 80; in two, 86; in one, 89; in four, 100; in ten, from 110 to 125; in eight, 130; in two, 145; in two, 150; in one, 180.

Of thirty-five infants, from one to two months old—in fourteen, the pulse was from 80 to 85; in one, from 60 to 62; in two, 90; in two, 94 and 95; in five, from 110 to 112; in two, 114; in seven, from 125 to 130; in three, 140, 147, 150.

Of eighteen infants from two to three months, there were fourteen whose pulse was above 90; in two, it was above 100; in two others, 73; in two, from 70 to 80.—(*Traité des Maladies des Enfants*, 1829.)

Little reliance, therefore, can be placed on the pulse of infants during disease, and consequently it is seldom felt.

The respiration, which is so essential to the arterialisation of the blood, is proportionally rapid; it is from 35 to 40, or even more, in a minute; while that of the adult is from 18 to 20. The rapidity of the circulation propels the blood into all the tissues of the body, and accounts for the redness of every part, of the skin, brain, bones, &c. Hence, when these parts are inflamed, and consequently contain more blood than usual, and the supply being kept up, we find it more difficult to arrest the mischief, and this explains the frequency and rapid fatality of inflammatory diseases. This fact should be ever kept in mind in our treatment of inflammations in early life. The extreme vascularity of all the textures in the infant, has led many writers to maintain the predominance of inflammatory affections over all others.

The source of growth is nutrition, and therefore the digestive, circulatory, and respiratory systems, which are most engaged in this function, predominate during infancy.

The lining membrane of the lips, gums, tongue, cheeks, and throat, is continued into the air-passages and lungs, and along the œsophagus, stomach, and intestines; it is of a deep red colour, and highly vascular. The irritability of this membrane is often such as to render it unable to bear the stimulation of the commonest food, or sometimes even the mother's milk. When the intestinal lining or mucous membrane is irritated or inflamed, it secretes a large quantity of mucus, and this we often observe in the diarrhoea of infants. When the pulmonic portion of the membrane is irritated by cold, a copious secretion also takes place, and causes the wheezing and rattling which are heard when a child is said to have taken cold.

The skin acquires less sensibility by degrees, the senses gradually become accustomed to external impressions, the intelligence progressively improves: but it is a long time before the infant can recognise the objects connected with its wants, as aliment, &c.; and the first signs of mental development are evinced by its endeavouring to touch those objects which have fallen under its vision.

After a certain time, which will vary according to infantile development, sex, climate, and state of health, a train of new circumstances commence; the maternal aliment ceases, the infant is gifted with teeth for the mastication of more solid nutriment, and the power of articulation, or speech, soon follows.

A new-born infant has no need of teeth, because nature does not intend that it should masticate or drink the aliment she has prepared for it in the maternal bosom. Some infants, however, are born with teeth, as the annals of medicine amply attest. Haller cites nineteen examples; and it is a fact attested in history, that Louis XIV. had four incisor teeth at birth. This phenomenon has been observed in infants born prematurely, as well as in those whose nativity was protracted beyond the usual term of pregnancy.

The rudiments of the teeth have been observed in the fifth month of pregnancy; and, according to M. Capuron, commence, perhaps, at conception. The teeth do not appear at any precise time, or in regular order, though the two middle front teeth of the lower jaw, called *incisors*, generally appear about the fourth or fifth month. There are many instances on record in which they appeared at birth, and many in which they did not pass through the gum until the twelfth or eighteenth month, and even for years. But in general about the time already stated, the two middle incisor teeth of the lower jaw appear; and about two or three weeks, or the sixth month, the two opposite ones in the upper jaw escape through the gum. About the eighth month, the two lateral incisors of the lower jaw are

protruded, and soon afterwards the two corresponding superiorly.

Before the completion of the first year, the whole of the incisors will have appeared, generally, however, at irregular intervals; and sometimes one or two of the *molars*, or grinding teeth, may precede them. In most cases the foremost grinder of the lower jaw escapes first, and next the *canine* or eye teeth. The latter are often very troublesome; and it is indispensably necessary to cut the gum, sometimes more than once.

About the end of the first year, or later, perhaps at the fifteenth month, we observe eight *incisors* and four grinders. During the second year, and at very irregular periods, the last or innermost grinders of both jaws appear, and complete the milk-teeth to the number of ten in each jaw. About the age of four years and a half, four other molar teeth pierce the gum. These are also called *deciduous* teeth, because they fall out after a certain time, and are too small for the adult. They are to be speedily replaced by the permanent set.

The completion of the eruption of the milk-teeth is an important period of infantile life. There is no longer irritation in the gums; and that which was excited in the head, chest, and abdomen disappears. Nature has now supplied the infant with the means of masticating more solid aliment than that afforded by the mother, and indicates the necessity of weaning. The bones have become firmer and stronger, and the whole body more developed and vigorous.

It is worthy of notice that, when the infant is healthful, dentition commences about the fourth month, and sometimes earlier; and, like all other functions of the body, is effected without inconvenience. But when the physical and moral education of the infant have been badly conducted, it is delicate and irritable, and teething becomes productive of serious mischief, and may induce convulsions, diarrhoea, or water in the head. It would be inconsistent with the usual course of nature, that the development of the teeth should be productive of more pain and danger than the growth of any other part of the body; and it would be contrary to the unbounded goodness of Divine Providence, that so many tender infants should be doomed by dentition to the severest sufferings, nay to death itself. The cause is mismanagement of physical education, and not the intention of the great and beneficent Author of all good.

About the fourth or fifth month, sometimes earlier or later, we usually observe an increased flow of saliva, the infant becomes restless and fretful, the bowels become deranged, the breast milk is vomited in a curdled state, or there is diarrhoea, and sometimes a frequent evacuation of urine. The skin becomes covered, either partially or generally, with some kind of eruption, the mouth and gums are found hot and painful, and perceptibly redder

and fuller at one or more points, and the infant conveys every thing it can lay hold of to its mouth, and compresses its gums upon it. Sometimes there is rapid emaciation, with flabbiness of the flesh, and high fever or diarrhoea. In some instances there is not an increased flow of saliva, or any derangement of the stomach or bowels; and in such cases the head is very liable to become affected, and there is great danger of convulsions or hydrocephalus. All these irritations and diseases are excited by the pressure of one or more teeth on the nerves in the gums; and in the same manner as local irritation in any part of the body, may throw the whole into disorder, as a slight wound induces tetanus or spasm of the whole muscles.

The second dentition usually commences about the age of seven years, the jaw grows, the milk-teeth are separated from each other, decay, fall out in the order of their eruption, or require removal, and are replaced by the permanent or adult set, which continue through life. The molar teeth sometimes remain, and about the tenth or twelfth year four others appear, making twenty-eight in number. Sometimes the milk-teeth do not fall out, and the second set protrude, forming a double row. Between the ninth and tenth years the incisors and canine teeth have appeared; and before the twelfth year the smaller grinders have followed. Between the twelfth and twentieth years the two larger grinders make their appearance.

A third dentition may be said to take place between the twenty-seventh and thirtieth years, when the wise teeth, or *dentes sapientiae* appear, and complete the number of thirty or thirty-two.

The milk-teeth are twenty in number. The secondary teeth are separated from the primary by an osseous partition. The permanent tooth comes in contact with the primary one, which it is to replace, and causes absorption of the fang of the latter. Mr. Hunter denied that absorption of the primary tooth takes place; while Chaussier and Richat ascribed the falling out of the milk-teeth to the absorption of the phosphate of lime.

In general, the teeth increase from above downwards, from the head to the root. The fang is opposed by the osseous partition, and the crown of the teeth is forced through the gum, which it thins by exciting the absorbents into action,—the infant cuts its teeth.

The absorption of the gum is not always effected in the same manner, or with equal rapidity; and hence there are anomalies and irregularities during the first dentition. Some infants cut their teeth precociously, and others very slowly. Precocious teeth become decayed, or fall out soon after their eruption, and are seen in the most delicate infants. We observe, on the contrary, that some infants do not cut their teeth until twelve, eighteen, or twenty months have elapsed; and some persons have no teeth at all. A gentleman w^t

attended these lectures about five years ago had not a single tooth. He died soon afterwards. In some the gums are ossified. Plutarch and Valerius Maximus relate that Pyrrhus, King of Epirus, and one of the sons of Prusias, King of Bithynia was in this condition. There are numerous authors cited by Dr. Mason Good, in his learned and elaborate *Study of Medicine*, attesting this fact, and a variety of anomalies regarding dentition. Some persons at the age of seventy, and even older, had a new set of teeth afforded them, or their gums were ossified. Professor Capuron states that Bernard Gengha found a skull in the Hospital of the Holy Spirit at Rome without a lower jaw, and with three teeth only. Professor Dewees observes, in his sensible and judicious work on the *Physical and Medical Treatment of Children*,—"1. Sometimes children are born with teeth ready cut, but this precocity is no proof of vigour of constitution. 2. Sometimes the latter cut themselves before the middle ones; at other times the canine may be seen before the incisors. 3. Now and then the teeth are very tardy in showing themselves. We have several times seen the first tooth make its appearance after the fourteenth month; and Van Swieten mentions an instance where this did not happen till the eighteenth month, though the child was perfectly healthy; and a child is now under our care, who has not yet cut a tooth, though rather beyond seventeen months old. 4. Rayer mentions a case where the teeth did not appear till the child was thirteen years old. 5. Fouchard relates an instance where, at six years old, the child had but one foretooth. 6. Brouzet gives an instance where only one half of the proper number of teeth was present at the twelfth year of the child's life, and whose gums had acquired the hardness of an old person's. 7. Professor Beaumes gives the history of a man, in whom no teeth ever appeared."

The teeth present many other varieties in the order of their eruption. The middle superior incisors may appear before the lower; the four molar before the canine or eye-teeth, or even before the incisors; and the large molar before the smaller ones.

Dentition is more rapid in vigorous infants, and is very slow in those that are lymphatic, as the scrofulous or ricketty. The eruption of the molars or grinders is generally attended with more suffering than the incisors; and this is easily accounted for, by the difference of the crowns which have to escape through the gums.

Sometimes the canine, eye, or angular teeth pass through the gum with great pain and difficulty; and it often happens that the permanent tooth will protrude either inside or outside the former. In such cases the removal of the milk-tooth will be advisable.

As it generally happens that there is more or less irritation caused by dentition, nature endeavours to obviate it in a great measure,

by placing an interval between the appearances of the teeth.

As to the secrets of empirics, anodyne necklaces, vegetable syrups, &c., for facilitating dentition, as well as all superstitious remedies, they are, I need not say, useless and absurd. The rational and judicious management of dentition deserves serious attention. The bowels should be regulated; the physical management as to diet, clothing, &c., duly attended to. An occasional warm bath diminishes the local as well as the general irritation in the system. The quality and quantity of aliment should be regulated, because the mucous membrane of the mouth, which is continued into the respiratory and digestive organs, may become speedily irritated by sympathy. If the infant is at the breast, the mother should avoid all high-seasoned or spiced foods, all spirituous liquors, so as to render her milk free from stimulating properties. If the infant is weaned, its food ought to be laxative; in a word, every source of irritation to its moral and physical states should be carefully avoided. Slight friction of the gums sometimes affords relief and excites absorption, or, as the vulgar suppose, expedites the cutting of the teeth: in other cases it is intolerable. All kinds of metallic, ivory, or glass instruments, corals, &c., are too hard, and are only calculated to contuse, wound, or inflame the gums. A crust of bread, a piece of liquorice root, or an India-rubber ring, is preferable.

The prophylactic treatment, or that which prevents disease, must be modified according to temperament and symptoms. There is one remedy of immense advantage in facilitating the eruption of the teeth, and that is, incision of the gum. This is by no means so painful an operation as is generally supposed; and I have often performed it without the infant uttering a murmur. It is, however, painful in the majority of instances, but is indispensable, as I shall prove hereafter, when describing more fully the treatment of dentition. I am convinced that it prevents the majority of diseases caused by teething,—such as convulsions, diarrhoea, inflammation of the brain and mucous membranes of the lungs and bowels.

It is a bad practice to administer large doses of soothing syrups for the purpose of inducing sleep; and great caution is necessary even in applying them to the gums, as they may be swallowed, and cause narcotism or death.

When the milk-teeth have protruded they are very readily injured and decayed by soft sugar, which contains an acid that proves destructive to the enamel. All sweet aliments and very warm fluids are injurious to the teeth in infancy and childhood. Children should not be allowed to crack nuts, almonds, &c., with their teeth, as the concussion will shake or loosen them, and accelerate their decay. When a child or adult suffers from toothache arising from decay, pure nitric acid will afford immediate relief. I believe I was the first who proposed this remedy, at least who pub-

lished its efficacy. Before I ventured to do so, I referred to a great number of works both ancient and modern, but did not find it recommended in any one of them. One individual asserting that he had known the efficacy of the remedy eight or nine years before, I drew the attention of the profession to it in the Medical and Surgical Journal; but it was rather remarkable that he kept his own secret, admitting his claim to be true; and had I not published, he would have probably carried it with him to the grave. The acid should be pure and strong; and the best mode of applying it is by means of a gold, platina, or glass probe covered with lint. The whole of the carious surface must be touched, and the mouth washed with tepid water. There is no pain produced, in ordinary cases of toothach, when application is made early; but should the nerve be inflamed and the cheek swollen, then acute suffering may be produced, though most certainly in very few cases. The remedy is most successful when applied to the lower teeth, because it seldom touches the whole of the caries in the upper. I have used it in a vast number of cases of children, and of delicate and pregnant women, with the most gratifying results. It is a good practice for preserving the teeth, to wash the mouth with tepid water, morning and evening, and some recommend it after each repast.

The term *infancy* is applied from birth to the seventh year, and *childhood* from the seventh to the fourteenth, or to puberty. Each period is characterised by peculiarities, as we see well attested in physiological works. It is now ascertained that ten infants die during infancy to the one that perishes during childhood. The diseases of the latter period are highly dangerous, and are generally of the inflammatory kind; but, as the constitution is generally more vigorous, the majority of feeble infants having been previously destroyed, the mortality is not so great.

In the moral and physical education, and in the treatment of infantile diseases, the corporeal and mental peculiarities must be kept always in view. This is a medical axiom, and its validity did not escape the great observers of nature in ancient times:—

“*Ætatis cujusve notandi sunt tibi mores,
Mobilibusque decor naturis dandus et annis.
Reddere qui voces jam scit puer, et pede certo
Signat humum, gestit paribus colludere, et
iram
Colligit, et ponit temere, et mutatur in
horas.*”

When the first dentition is completed, and infancy has merged into childhood, all the functions and all the organs improve, and advance until the age of puberty. At this period maternal care is diminished; and the diseases which occur are, to a great extent, treated upon ordinary principles.

It is a remarkable fact, that all infants are generally of the same figure whether male or

female, and have the same or the mixed temperaments, constitutions, mental and corporeal condition, and diseases of parents. Some infants are like the father, others the mother, and some have no resemblance to either. The diversity of age, the ardor of love, and the state of life and of season in which conception takes place, establish the greatest difference between infants of the same marriage. There are numerous proofs in attestation of the validity of this conclusion in my work on Midwifery.

When children do not resemble either father or mother, it is because the traits of both are so intimately mixed as to be effaced. But, in general, the resemblance between parents and children is striking, and it is reasonable to conclude, that if an infant has the same conformation of its external organs as those of its father or mother, so it will have those of the internal, and possess the same or a very similar constitution, temperament, and predisposition to disease. The similitude of constitution and disposition between parents and children is universally admitted. It therefore follows, that as the conformation and action of the external and internal organs of children depend, in a great measure, upon those of parents, we are led to the conclusion, that an aptitude to transmit certain diseases is imparted, and that some diseases are hereditary.

Every individual receives from his parents a particular organisation, which generally renders one of the organs more feeble than the rest, and consequently more predisposed to disease. Different diseases are developed at different periods of life. In infancy scrofula attacks the glands of the neck, the bones become deformed or rachitic; after puberty the lower extremities and the spine become deformed. It is also well known that eruptive fevers, as measles, small-pox, and scarlatina are more common in infancy than in any other period of life. Dentition is also peculiar to this period.

The other causes of infantile diseases are very numerous, in consequence of the superabundance of activity in all organs, the delicacy of constitution, and the innumerable external agents to which the infant is exposed. The life of man after birth is subjected to many dangers, and these I have fully noticed in my account of the hygiene of infancy. The greatest of these are the exhibition of improper food, exposure to cold, dentition, and inattention to the precepts on diet, clothing, cleanliness, sleep, exercise, and the other subjects discussed on a former occasion. The most prolific causes of infantile diseases are the aliments and elements.

I have mentioned on a former occasion that every description of food, unless the milk of a healthful mother or nurse, or that of the ass or cow, is improper or injurious to new-born infants. Nature supplies, in most cases, the proper aliment; and every deviation from it is a violation of her dictates. She never intended that a new-born infant should be nou-

rished with farinaceous substances, such as water-gruel, arrow-root, pap, bread, &c.; and these excite irritation of the lining membrane of the stomach and bowels, causing hiccup, griping, unnatural stools, inflammation, ulceration of the alimentary canal, and very often death itself. In nine instances of ten, both mothers and nurses overfeed infants, as they generally imagine they cannot give too much food. The stomach is pained by improper food, more especially if over-distended, irritation is excited, and nature expels the offending cause by vomiting. The infant is in pain during and after vomiting, it cries or screams, it is said to be hungry, and is again overfed until it vomits. The stomach becomes more irritable by repeated excitement, the infant screams incessantly, and now the nurse displays her skill, by exhibiting some cordial or soothing syrup, diacodium or syrup of poppies, Godfrey's cordial, Dalby's carminative, syrup of soot, syrup of violets, oil of aniseed, &c., or some ardent spirit, as brandy, whiskey, rum, gin, &c. Every one of these is highly improper, and increases the irritation to such a degree, that the unfortunate little sufferer screams incessantly, and at length is relieved by the judicious treatment of a medical practitioner. Millions of infants are annually destroyed by improper food, and repletion, or overfeeding. These fertile sources of mortality extend to children who are generally allowed solid animal food, puddings, pastry, unripe fruits, too much porter, wine, and, among the lower classes of society, ardent spirits. Tea, coffee, chocolate, or cocoa, &c., are also injurious. In a former lecture I described the proper aliment for children. How often do we observe gratification of the palate, the only incentive held out to children for good conduct. A moderate use of fermented liquors would not be injurious, but an excess of them is highly prejudicial.

Exposure to cold is the second great cause of infantile diseases, and this is so universally known, that I need not expatiate upon it. Every one knows that cold is the commonest cause of inflammations of the external and internal organs, of fevers, and almost all diseases; and hence the imperious necessity of protecting infants and children against its influence. I have already dwelt upon this subject when describing the dress of infants.

In recapitulation I may observe, that the chief causes of infantile diseases are, privation of maternal lactation, the substitution of improper aliment, exposure to cold, vicissitudes of season, bad air, filth, errors in diet, clothing, exercise, repose, improper moral management, precocious mental cultivation, contagions, as small-pox, measles, scarlatina, hooping-cough, &c. The transmission of a feeble, delicate, or diseased constitution, is a predisposing cause of diseases. We see this fact well exemplified in all large cities, and also in manufacturing towns, where women labour as well as their husbands, and are exposed to many privations,

vicious habits, improvidence, and intemperance. The lower classes are crowded together in filthy and unwholesome abodes, they are prone to drunkenness, infected with diseases induced by licentiousness, which are communicable to offspring. Their depravity is so great that many of them refuse to enter the marriage state, or enter this condition too early, and the result is enfeebled and diseased infants, which are readily destroyed by poverty, contagious diseases, and every sort of mismanagement. It is proved beyond doubt that the mortality at Manchester and Glasgow, both manufacturing towns, is much greater among infants than in the largest cities. (Robertson on the Mortality and Physical Management of Children, 1827.) This able writer gives a table of the proportion of illegitimate children in different places, which shows some curious results. He states that the proportion of illegitimate children at Manchester is 1 in 12; in Paris, after the revolution, 1 in 11, and in 1821 and 1822, 1 in 3, or 36 per cent.; in Stockholm 1 in 3; and in Sweden and Finland 1 in 20. It is difficult to ascertain the proportion of illegitimate to legitimate births in this capital, but I believe it to be very large. The mortality of such children is immense; Dr. Caspar informs us that 3 per cent of the children born in wedlock in Gottingen are born dead, and 15 per cent of the illegitimate. In Berlin, in 1819 and 1822, the deaths of the infants born in marriage were 1 in 25, of the illegitimate 1 in 10. The mortality of illegitimate infants born alive, and of legitimate, is also proportionally great. "For 10 legitimate infants who die in the first month, there are 24 illegitimate. In the second and third months the proportion is two to one. In the second quarter it is one and three-quarters to one. In the two remaining quarters of the first year it is one and one-half to one. In the second year, one and two-fifths; in the third and fourth years, one and one-third. In the fifth, sixth, and seventh, one and a quarter; and of the total number of natural children, only one-tenth or one-ninth pass the age of puberty." (Medical Statistics, &c.) We cannot be surprised at this mortality, when we consider that most of the illegitimate children are produced before the adult age, by dissipated parents, often debilitated by hard labour, intemperance, and vicious habits of all sorts, and that all the sacred duties of parents, especially those relating to physical education, are neglected. Mr. Robertson makes some apposite remarks on this point, and also on early marriages, which are worthy of citation. He says, "Moreover early marriages, though they cannot be called vicious, are always common where the means of subsistence fluctuate to both extremes. Their effect is to produce feeble children, and afterwards to starve such of them as might, under other circumstances, be reared.

"But without adverting to the vices of the

poor, how often do we see the mother of a large family obliged to follow some employment besides the care of her household, and that too at a distance from home. Meanwhile her children are unavoidably neglected. Besides, the abject poverty from which those who subsist by manufactures are never long exempt, occasionally renders it impossible for the poor to feed and clothe their families in a manner compatible with even ordinary health. To such causes of debility and disease, when we add filthiness, impure air, want of exercise, the great liability to infectious complaints, at a very early age, in crowded neighbourhoods, mismanagement in health and sickness, especially the shocking practice of exhibiting spirituous liquors even to infants at the breast, and want of medical treatment, we readily perceive why infantile mortality is greatest where the poor are most numerous; and that it must increase in manufacturing districts, *cæteris paribus*, in ratio of the increase of the operative population." This excellent observer goes on to state, that a friend informed him of a custom among the poor at Manchester which is common in all parts of the United Kingdom—a landlord of a dram shop stated "that he was in the daily habit of seeing mothers pour undiluted spirits into their infants," "sometimes," as he expressed it, "till they became black in the face." If they showed much aversion at first, the finger was dipped in the liquor, until the taste for it was acquired.
